Pseudarthrosis of the hip-joint.—Mr. R. G. TAYLOR (Oxford) had studied the late results in 93 patients treated for osteo-arthritis of the hip, ankylosing spondylitis, and other conditions by excision of the head and neck of the femur. The result was good in 83 cases and poor in 7; 3 patients died as a result of the operation. In successful cases the benefit was permanent. Pseudarthrosis was the most satisfactory and the most reliable operation in ankylosing spondylitis, and in patients over 60 years of age with disabling osteo-arthritis. Cup arthroplasty might prove to be superior in younger patients with osteo-arthritis.

Treatment of Volkmann's contracture.—Mr. A. R. PARKES (Glasgow) had treated 2 patients with established Volkmann's contracture by tendon transplantation designed to restore independent action to the flexor digitorum profundus tendons without interfering with active movement at the wrist. The operation consisted in division of the contracted finger flexors (sublimis and profundus), division of contracted wrist flexors, and transfer of extensor carpi radialis longus to the distal stumps of the profundus tendons above the transverse carpal ligament. The results had been promising. Mr. D. L. GRIFFITHS (Manchester) recalled that the extensor muscles were often affected in Volkmann's ischæmia. Before undertaking this operation, it was necessary to be quite certain that there was adequate voluntary power in the wrist dorsiflexors. Mr. H. J. SEDDON hoped that the operation might reduce the indications for prolonged stretching of the contracted tissues, and for such operations as shortening of the forearm bones. The muscles affected most seriously by ischæmia were the flexor digitorum profundus and flexor pollicis longus. Involvement of the superficial flexors was often relatively slight, and their action could be adequately reinforced by transplants. Arthrodesis of the wrist made available sufficient extensor tendons for transfer to flexor pollicis longus as well as to the finger flexors.

Tendon growth in the rabbit.—Dr. G. N. C. CRAWFORD (Oxford) had placed multiple indian-ink marks along the length of suitable tendons of growing rabbits, and had measured the intervals between the marks. The same intervals were measured again after killing the rabbits three to four months later. Tendon grew interstitially throughout its length; and the most rapid growth was near the muscle-tendon junction.

Amputations of lower limb for vascular disease.—Mr. HARMAN SMITH had examined 138 amputation stumps in 95 patients with primary vascular disease of the lower limbs. The object had been to assess the criteria that could be relied upon to determine whether below-knee amputation was likely to be adequate. Of 81 below-knee stumps, 27 had proved satisfactory and 54 unsatisfactory. The most significant factors were age, the state of the popliteal pulse, and the amount of bleeding at operation. The most valuable criterion was the amount of bleeding at operation and the appearance of the muscles. When bleeding was sluggish and the muscles grey, amputation at a higher level was indicated; but when free bleeding occurred from healthy muscles a satisfactory stump could be expected. Used in conjunction with other tests of circulatory function (skin-temperature tests, tourniquet tests, and oscillometry) these criteria were reasonably reliable in indicating the lowest practicable level for amputation.

Histology of bony union.—Mr. JOHN CHARNLEY (Manchester) showed histological sections taken from the line of arthrodesis at various intervals after "compression" arthrodesis of the knee. He demonstrated convincingly that the line of fusion was bridged by trabeculæ of woven bone as early as four weeks after operation. At eight weeks, healing by fully established woven bone was almost mature. It was still uncertain whether this rapid bony union was determined by pressure or simply by close apposition of the fragments.

Monteggia fracture.—Mr. J. H. PENROSE (Bristol) reported 7 cases of Monteggia fracture with posterior dislocation of the radial head. He suggested that the mechanism of the injury was similar to that which caused posterior dislocation of the elbow—a fall on to the hand, the elbow being slightly flexed and the forearm in moderate pronation. In every case there was a marginal fracture of the head of the radius. Treatment was by intramedullary fixation of the ulna and excision of the radial head or of the detached fragment. All patients regained good function, but some limitation of elbow movements was usual. Mr. E. MERVYN EVANS (Birmingham) thought that closed manipulation —by full extension and supination—should be tried before open operation was resorted to.

Movements of the tarsus.—Mr. EDMUND SHEPHARD had observed the movements of the tarsal joints in living and dead feet. Only two movements were possible: supination (combined inversion and adduction) and pronation (combined eversion and abduction). These movements might take place at the peritalar joint or at the midtarsal joint. The peritalar joint comprised the talonavicular joint and the subtaloid joint; its mechanism was comparable to that of the radio-ulnar joints. The peritalar joint allowed a wide range of supination and pronation about an axis directed obliquely downwards and backwards through the body of the talus. The midtarsal joint allowed a small range of supination and pronation about a similar axis.

Fracture of the lateral malleolus.—Mr. DAVID THOMAS (Scunthorpe) presented an analysis of 109 stable fractures of the lateral malleolus—59 treated by immobilisation

THE LANCET

LONDON: SATURDAY, MAY 20, 1950

Anomalies of Salary

If we had chosen to have a State medical service on the military model, the remuneration of doctors would have been simple and straightforward. Everyone in the service would have been employed directly by the Minister of Health, who would have paid him the salary belonging to his rank. But a hierarchical system of this kind was unacceptable, and instead we have devised one in which the large majority of doctors are neither officials nor Civil Servants but private persons working by contract with one or other of the more or less autonomous bodies which have been created to administer the service. So we have a state of affairs in which, though nearly all the money ultimately comes from the Treasury, some doctors are paid directly by the Government, some by local authorities, some by regional hospital boards, some by the boards of governors of teaching hospitals, some by universities, some by hospital management committees, and some by local executive councils. This ingenious system goes far to meet professional susceptibilities and preserve valuable traditions of work; but unfortunately, at its present stage of development, it also embodies some anomalies which are intolerable in a service which was made national in order that it could be rational. These anomalies arise chiefly from the fact that, while the new administrative bodies (the regional boards, the executive councils, and so on) pay their doctors at new rates, based on the recommendations of the two Spens Committees, the administrative bodies that existed before the Act was passed (the Government departments and local authorities) have so far failed to make the changes needed to bring their remuneration into line.

Big differences in rates of pay are least defensible where doctors in different branches of national service are doing the same work under similar conditions. The classical example is provided by the Ministry of Pensions, which seems to think it proper that the senior physicians and surgeons clinically responsible for the work of its hospitals should still, in 1950, be paid at rates round about £1000 a year, or only a couple of hundred pounds more than their senior residents. If the Ministry of Pensions hospitals were small antiquated buildings which attempted only a primitive form of medical care, for a small group of chronic disabilities, this might be more excusable. But in fact some of them are large hospitals undertaking advanced work. The operation list of a senior surgeon at a Ministry of Pensions hospital is often just like the operation list of his colleague in the National Health Service hospital across the road, whose salary is probably some £1500 a year higher: and the situation is becoming more absurd now that Ministry of Pensions hospitals admit and treat considerable numbers of N.H.S. patients. Clearly the Ministry cannot be allowed indefinitely to pursue a policy which must end in its having an incompetent staff. Its record must lead many to ask again whether there is any sufficient reason why its hospitals should not be transferred to the National Health Service.

Many of these arguments apply, equally or with modifications, to the situation of other clinicians working in Government medical services—e.g., in the Post Office or the prisons. The time has surely come when the departments concerned should realise that if they want specialists or other doctors with first-rate qualifications to accept clinical appointments they will have to pay the rate for the job, as laid down by the N.H.S. Application of this rule, however, would still not solve the problem of the doctor who has entered the service of local or central government as an official—the medical officer of health and his assistants, and the medical officers of the Ministry of Health or the Factory Department. Salary scales for the M.O.H. are now, after long delay, being considered by the public-health committee of the medical Whitley Council; so they cannot usefully be discussed for the moment. But the attempt to gain better remuneration for medical Civil Servants has been brought into the foreground of controversy by the exchange of letters with the Chancellor of the Exchequer, and by the British Medical Association's subsequent decision to discontinue advertisement of Civil Service medical appointments in the columns of the *British Medical Journal*. In this dispute the arguments are briefly these. The Treasury holds that a doctor who enters the Civil Service accepts the known conditions thereof, one of which is that his salary will be slightly lower than that of an administrator of corresponding grade. In relation to other walks of life, the Civil Service has always been poorly paid, but it offers certain countervailing advantages. When the Chorley Committee's scales are applied (as, but for the devaluation crisis, they would have been last October) medical officers with salaries of £1500 or over will benefit with their lay colleagues, and some day there will no doubt be a corresponding improvement in the pay of junior medical officers: but so long as the Government are urging organised labour to accept a wage-freeze, any rise at all would be most inopportune. To these Treasury arguments the reply is that the advantages of belonging to the Civil Service are no longer what they used to be, and that if it is to handle large new technical undertakings such as the National Health Service it must have technicians of high quality in its departments and must create the new conditions which will attract and keep them. In its dealings with atomic scientists, the Treasury has recognised the existence of the law of supply and demand, and has gone outside the previous range of remuneration. At the Ministry of Health, on the other hand, it has preferred to keep to Civil Service precedent, even though this has meant losing expert staff. Instead of having freedom to pick the best medical talent for key positions on the Ministry's side of the new service, the chief medical officer has had to watch many of his younger men slip away one by one—often to posts in the N.H.S. which were less important but better paid. The danger of this Treasury policy is not that the Minister of Health will one day wake up to find that he has no medical officers at all: it is that, failing an adequate supply of really capable men with pensions or other private means, some of the posts will be filled by people who are not up to standard. Of this danger the Minister and the

the exact location, or describe the vegetation surrounding his pollen station, though pollen incidence may vary widely between any two stations only a mile or two apart. In a brief discussion on the effect of weather on "pollination" (a term which has another sense here, but which he uses for pollen liberation) he makes statements which have been shown not to be generally true.

The greater part of the book is an atlas of airborne pollens and spores; and a good atlas of this kind has long been wanted. Some 32 types of pollen are included, among them 16 of the 30 or so chief types to be met with in Great Britain. Each type is briefly characterised in simple language and figured three times—by means of a simplified diagram, an enlarged drawing, and a photomicrograph. Dr. Brown pins his faith to the "dry pollen technique"; that is, he mounts and examines his pollens in soft paraffin, claiming that "many of the common hayfever pollens are more easily recognised [thus] than in any other condition." Several examples could, however, be quoted to show that essential diagnostic features, which are easily demonstrable by other techniques, are not mentioned by Dr. Brown, and do not appear in his illustrations. He even admits that the single pore which distinguishes grass pollens "does not show when the pollen is in the dry state."

Pollen iconography is a difficult art, and Dr. Brown has not overcome the difficulties. His photographs serve only to indicate the size and general shape of the grains, and his drawings only partly make up the deficiency. He illustrates only a few types of fungus spores and some of these present an unfamiliar appearance. The book is beautifully produced but it cannot be recommended without reservation.

Bermondsey Story

The Life of Alfred Salter. FENNER BROCKWAY. London: Allen & Unwin. 1949. Pp. 246. 15*s.*

Mr. Fenner Brockway's brushwork never sparkles, but he paints a convincing portrait of a remarkable medical man. Alfred Salter had the capacity and opportunity to become a consulting physician or pathologist, but he chose general practice in Bermondsey. Such a choice may not be quite so rare or even so self-sacrificing as the author suggests; but Salter chose, further, to live, with wife and daughter, where he practised, to send this much-loved child to the local council school until a third attack of scarlet fever ended her life, to give up practice for political social service, and to spend himself without stint or reserve in promoting what he esteemed to be justice, truth, and beauty, and in fighting what he deemed to be their opponents.

The motive force in all this was a belief in the Christian ethic, acquired directly from his parents and actually lifelong, for a brief period of agnosticism in youth was ethically Christian, and in its essence religious. But the quality of the man, as here depicted, was as much Roman as Christian. *Integer vitæ, scelerisque purus, Justum et tenacem propositi virum*—the Horatian phrases fit him like a glove. One who, struck suddenly with complete aphasia in a snack-bar near King's Cross, could think out his route to Bermondsey by train and bus and make it good with no word spoken, knew well how to "keep the equal mind," *rebus in arduis.*

Salter is presented as a tireless advocate of "Socialism," but this elusive concept is nowhere defined; and it is clear that he, like so many Socialist heroes, was in fact an extreme individualist. His sole allegiance was to his conscience. He resisted alike decisions of Parliament and of local authorities, defied popular opinion with the utmost courage, and broke in turn with the Liberal Party, the I.L.P., the Labour Party, and ultimately even the Peace Pledge Union on grounds of principle consistently held. Not of such citizens, surely, could a working Socialist State be formed.

The book gives a notable account of British social history in the last fifty years, as seen from the Left and from Bermondsey. For municipal Socialism in a downtrodden area it makes an unanswerable case, but it avoids the wider issue of individual liberty versus dictated order. Salter's ideal State can only be guessed at, but it seems clear that though its citizens could be certain of justice none would be free either to drink with his friends or to take arms in any cause, however sacred; and it might well prove to be a State without music. A book provoking much thought.

Fifty Years in Midwifery

The Story of Annie McCall, M.D. Written and arranged by PATRICIA BARRASS. London: Health for All Publishing Co. 1950. Pp. 122. 6*s.*

Dr. Annie McCall spent her life in the service of childbearing women and it was the dearest wish of her closing days to leave the story on record as a challenge to our times. Her photograph, at the age of 86, on the title-page of Mrs. Barrass's labour of love reveals the forceful genius which possessed her. The achievement of the Clapham Maternity and the overspill of her restless spirit into tuberculosis, child health, and rehabilitation are widely recognised. But in posting her biographer her memory was brightest for those early formative years in Göttingen and Vienna and Berne, and the early chapters will be new to many.

The Road to Love

GWILYM O. ROBERTS, PH.D. London: Allen & Unwin. 1950. Pp. 230. 9*s.* 6*d.*

THIS book, directed to a popular audience, contains excellent material, is written by a pupil of Terman with a long research experience, and is presented with a foreword by Prof. William Brown and another by Mr. David Mace, PH.D. The merits of the material are, however, almost wholly defeated by the style of the writing. One probably loses more than one gains by describing the "young man devoid of understanding" (*Proverbs*, vii, 4–23) as "the halfbaked laddie whose sexual brakes failed to function," or by counselling the adolescent girl: "when the sex jack-in-the-box crisis begins to loom, sidetrack him charmingly." These quotations are typical. The manner is peculiarly unfortunate, because vulgarity and facetiousness are possibly even greater handicaps in work of this type than excessive moral earnestness, especially in dealing with an intelligent adolescent audience. The author summarises his advice on the regulation of sexual conduct "in the R.A.F. motto, *per ardua ad astra*"; but the adequacy of the exhortatory method, even when it is veiled in these terms, remains open to question. The emphasis on maturity and reasonableness is excellent, but readers will regret that the promise of the factual part of the book is not fulfilled.

Skin Grafting

(2nd ed.) JAMES BARRETT BROWN, M.D., professor of clinical surgery, Washington University; FRANK MCDOWELL, M.D., assistant professor of clinical surgery in the university. London and Philadelphia: J. B. Lippincott. 1949. Pp. 339. 60*s.*

THE first edition of this book was called *Skin Grafting in Burns.* In this second edition the authors have extended the scope to include skin grafting for defects caused by traumatic injuries, the removal of tumours, and the excision of areas which have been irradiated excessively. Thus it offers an adequate description of plastic surgical problems that may arise in any general hospital; but it does not include the treatment of congenital deformities, or the more complex problems that may be seen in a special hospital.

The pathology of burns is stated clearly and succinctly, and the methods recommended correspond closely to those in use in this country. Immediate treatment consists in careful cleansing and the application of massive dressings and compression bandages. Penicillin and blood are used as supportives. Split-skin grafts, applied reasonably early, are required for total skin losses; homografts are useful as a temporary cover. For final repair in bigger defects other varieties of graft may be required—full-thickness grafts, flaps, or tube pedicles. Their employment is discussed and illustrated by photographs of good quality, and the methods again conform in the main to those used here. The book will be useful to anyone concerned with soft-tissue repair.

ON April 29 we published an advertisement for Prof. Harry Gold's new book, *Quinidine in Disorders of the Heart*, published by Messrs. Cassell & Co. The price of this work is 16*s.*—not 6*s.* as might be supposed from looking at some of the copies we issued.

isolated in various laboratory animals, and gives highly specific agglutination or complement-fixation reactions with convalescent sera from Q fever patients. Antibodies persist on the average for two years, and occasionally for as long as seven years after infection, so a serological survey of a "normal" population will yield information covering several years of its past experience. It is not surprising, therefore, that these ideal qualities, combined with the intensive investigations of the last five years, have produced almost an embarrassment of epidemiological riches. The presence of *R. burneti* has been detected in so many situations—animal, arthropod, and inanimate—in the environment of cases of the disease that it is pertinent to ask where its presence is significant as a source of human infection and where it is merely an incidental finding.

The Australian studies [9] from 1935 to 1942 detected 129 cases of Q fever in Brisbane and 47 in the surrounding countryside; 123 of the urban patients worked in meat-packing plants and 39 of the rural ones were dairy workers or exposed to farm stock. The results may have been influenced by selective case-finding, for 116 of the urban cases came from one plant; nevertheless, occupational exposure to cattle seemed to be the important factor in contracting the disease. Serological evidence of infection was found in cattle, but direct contact with cattle organs by handling them during slaughtering and processing was probably not the cause of human infection, because cases were distributed throughout the meat-packing plants and not confined to those actually touching the carcasses. A wider search for *R. burneti* revealed that the bandicoot, a small bush animal, and its tick, *Hæmaphysalis humerosa*, were infected, and since some of the cattle ticks (*Boophilus annulatus microplus* and *Hæmaphysalis bispinosa*) could be experimentally infected, **Derrick** [9] postulated that the infection was probably maintained in nature by a tick-bandicoot cycle with a secondary spread to cattle via their ticks. Man was presumed to be infected by the inhalation of dust containing dried tick excreta from the hides of cattle. Infection by tick bite was thought to be an uncommon means of infection. Epidemiological investigations [5] of the outbreaks of Q fever among American troops in Italy showed that person-to-person spread was unlikely, and that dust contaminated by animals was a possible mode of infection. In one particularly striking episode 20–30% of an infantry battalion contracted the disease, probably having been infected during the showing of combat-training films in a hay barn.

Valuable additions to our knowledge of the epidemiology of Q fever have been made by the special team studying the disease in the endemic area of southern California. A preliminary field study of 300 cases in and about Los Angeles indicated that residence near dairies (in California this means a place where cattle are stalled, fed, and milked), occupational exposure to cows, sheep, goats, or their fresh products, and the consumption of raw milk containing *R. burneti* were probably the means of infection. The discovery [10] that raw milk from many of the dairy herds was infected with *R. burneti* was an early and entirely new finding. Observations on naturally infected cows show that they may have a chronic and practically symptomless infection of the udder and may shed rickettsia in their milk over long periods. It is not clear from experiments whether the disease of the udder represents the final localisation of a systemic infection or whether the udder is infected in some more direct way.

The epidemiological findings in the initial study regarding occupation, residence, and the use of raw milk were highly suggestive, but their significance could not be established until the incidences of the disease in populations with and without these three attributes had been compared. **Bell** and his colleagues [11] have now obtained such controlled data from an excellently planned inquiry. They found that the incidence of positive complement-fixation tests with *R. burneti* among the employees was 1·2% in two aircraft plants, compared with 5·9% in meat-packing plants, 15·6% in hide and pelt plants, and 20·6% in dairies. The significance of drinking raw milk was demonstrated by showing that the incidence of positive complement-fixation tests in households using raw milk was 10·7%, compared with 0·9% in neighbouring households which did not use it. The importance of residence near dairy herds known to be infected was shown by their finding that the frequency of serological positives declined as the distance from the dairy increased. The effect of the interaction of these attributes was also analysed. It may be supposed that human infection in Los Angeles occurs in two ways. One is by the respiratory route, through inhalation of dust or other airborne particles derived from animal discharges, excreta, or other products, a finding which is in accord with the Australian and Mediterranean experience. It is interesting in this connection that **De Lay** et al.[12] have recently isolated *R. burneti* from the dust of sheep pens in northern California. The other possible mode of infection is consumption of raw milk or milk products containing *R. burneti*. Attempts to test these portals of entry by experimental infection in man have given rather confusing results. **Blanc** et al.[13] infected two patients and four observers who inhaled a heavily infected aerosol, but **Fonseca** et al.[14] failed to convey the infection by either the respiratory or alimentary routes. So many factors affect such experiments that it would be unwise to draw definite conclusions from the negative findings.

If the means of transfer of the disease from animals to man is now a little clearer, much remains to be discovered about the spread among animals. One of the striking facts about Q fever is the frequency with which the rickettsia has been isolated from various ixodid and argasid ticks. In many of these *R. burneti* has been shown to survive from one instar to the next and to be transmissible to the host animal at each stage. Further, trans-ovarian passage of

Chancellor are no doubt as well aware as anyone else, and the Chancellor in fact proposes to appoint a committee to go into the question of "the remuneration and the general salary structure of Civil Service doctors," and advise the Government on what changes can be made "when economic conditions allow improvements to be made in remuneration generally." This committee, however, is to consist of four administrators and only two doctors (one formerly of the Ministry and one formerly of the London County Council); and the B.M.A. therefore regards it as quite unsuited to the only kind of inquiry which would be worth having. If the Chancellor, instead of proposing what looks a little like a mechanism for repeating his own opinions after a decent interval, were to appoint a really representative committee to make a serious study of what is after all a serious problem, the B.M.A. would, we believe, regard the proposal as fair and would remove its embargo on the advertisement of Civil Service posts.

If we do not at present impose a corresponding embargo on advertisements in THE LANCET, it is not because we are satisfied, any more than the B.M.A., with the remuneration of doctors working in or for Government departments. We have every sympathy with the response of the B.M.A. council to the appeal from a small but important section of its members to protect their interests. Our own position, however, as an independent journal, is rather different. At first sight an embargo on the advertisements of a particular service may seem no more than a dignified form of protest; but in the last analysis it is a form of pressure applied with the deliberate object of making a service unworkable until those in charge of it give way. Pressure of this kind is permissible, in our view, when an individual employer does not apply some national scale; thus, like other medical journals, we have long been in the habit of refusing advertisements which are inconsistent with the Askwith agreement. Pressure seems permissible, again, where employers violate an established custom of the profession; and we regularly refuse advertisements which say that remuneration will be lower if the successful applicant is a woman doctor rather than a man. Thirdly, pressure can probably be justified when it is brought to bear on an employer who refuses to negotiate through the channels laid down for the purpose; and last year we joined in refusing advertisements for public-health appointments until the local authorities agreed to take part in the Whitley Council and use its machinery for arriving at new terms of service. But to employ direct action to force the Government to reverse a national policy is a rather different matter. In this case the policy is that defined two years ago in the white-paper on the stabilisation of personal incomes, by which the Government are trying to hold off a general and dangerous rise in the cost of living and therefore of the cost of exports. In rejecting the claim for improved remuneration of medical Civil Servants, the Chancellor said that he fully recognises the need to maintain the efficiency of medical establishments but thinks it even more important to maintain the policy of wages stabilisation. Expert opinion is increasingly doubtful whether this line can be held much longer at all points: the freezing of wages and salaries cannot be borne indefinitely when there is so much unfairness in their present allotment. But, as citizens, most of us would be sorry to see changes in the policy forced by direct action on the part of aggrieved sections of the community. Various groups indirectly employed by the Government, such as the lower-paid railwaymen and the teachers, have reasons no less strong than those of the medical Civil Servants for desiring revision of their pay, and our colleagues' powerful case could actually be weakened by presenting it too forcefully and out of context. What is needed is its unprejudiced consideration; and the proper atmosphere for this would be created by the appointment of the kind of committee for which the B.M.A. asks.

Epidemiology of Q Fever

Q FEVER must now be considered among the possible diagnoses in obscure cases of acute febrile illness in England, especially southern England, and more particularly if the signs are suggestive of atypical pneumonia. Only thirteen years have elapsed since DERRICK [1] found the ætiological agent in Queensland stock workers, and the infection has since been recognised almost all over the world. Shortly after DERRICK had isolated the organism in guineapigs, BURNET and FREEMAN [2] [3] adapted it to the mouse and recognised that it had the morphological characters of a rickettsia; DERRICK then gave it the specific name of *Rickettsia burneti*. In the first five years after its discovery a great deal of epidemiological and other work on Q fever was done in Australia, but elsewhere it was looked on as a medical curiosity of strictly localised distribution, in spite of the recovery of a similar rickettsia from ticks collected in Montana, U.S.A.[4] Several laboratory outbreaks of Q fever occurred in the U.S.A. in this period and two-thirds of the cases, including some of the mildest, had an atypical pneumonia as part of the systemic disease.

The first outbreaks of the naturally occurring disease outside Australia were dramatic enough. The arrival of large numbers of susceptible Allied and enemy troops in the Mediterranean area was followed in 1944 and 1945 by large-scale outbreaks of an illness variously labelled as "atypical pneumonia," "Balkan Grippe," "pyrexia of undetermined origin," and the like. Many of these were subsequently identified by laboratory studies [5] [6] as Q fever, and it was evident that Italy, Greece, and Corsica were endemic areas. In 1946, two outbreaks of the disease were recognised in stockyard employees at Amarillo (Texas)[7] and in Chicago,[8] and in 1947–48 an endemic area was found in California. Q fever has also been reported from France, Germany, Palestine, Switzerland, Spain, Turkey, South America, and Great Britain—in fact, in most places where it has been looked for. It is in many ways an ideal disease for combined bacteriological and epidemiological studies. The rickettsia is a hardy organism easily

and checking expenditure against the budget used to be considered the special province of the hospital administrator who knew his job. It is encouraging to see them coming once again to the fore; the Department of Health would find some other well-tried recipes, such as the use of quantity statistics and scrutiny of bed occupancy, in the now almost forgotten files of the 1920s and 30s. But Leviathan is bestirring himself, and if he maintains his energy will soon rediscover most of what can usefully be done by improving the system of hospital accounts.

So far so good; but it is no good overlooking the fact that there is still a serious flaw in the financial set-up which has nothing to do with the system of accountancy or techniques of financial control of the kind mentioned above. Why should any hospital unit bother about these refinements if savings are forfeit to the Exchequer? It would not do, we are told, to make outright allocations to the regional boards and thence to the hospital management committees; it would be inconsistent with the present system of governmental finance. That, no doubt, is true; but then the administrative framework of the hospital system is quite a new thing, and if we are going to give units at the periphery real administrative responsibility, and if we are going to ask them to sort out, in conjunction with their medical advisory committees, how the money had best be spent, we cannot at the same time say that they are not free to sort it out. We cannot tell them to go shopping and get the best value for money, and add as an afterthought that they must let us know in advance how they are going to spend it; or add that if they change their minds when they see the prices in the shops they will incur our displeasure and possibly a fine too—unless they have been pretty careless to begin with. Of course nobody at the Treasury or in the health departments sees the matter in this light; but that is because of the traditional divorce in public affairs between administration and finance, and the habit of thinking of them in separate compartments. As things stand today, the administrative framework of the hospital part of the Act, and the financial machinery being used to implement it, do not fit together; and one or the other will ultimately have to give way. So far the crucial nature of the struggle has been obscured by the flow of public money; and now that this is at an end it is imperative that the financial implications of the new model hospital system should be looked squarely in the face.

One last word. In typically British fashion we have indeed admitted a curious non-logical compromise; for it seems that regional boards have been allowed a power of approving the transfer of a "saving" from a head under-expended to one over-expended. Though this helps—and in some instances "helps" is too mild a word—to stave off the breakdown of the system, the device is open to serious criticism; for there is, of course, no true connection between overspending and saving, and the door is left wide open to the unscrupulous: what is easier than to overestimate this and that in the hope of pulling off a switch to something else? This half-permission to switch from one head to another is surely a snare, which serves only to obscure the need for clear thinking on the main issue.

Annotations

THE SPRINGS OF DELINQUENCY

EVEN among psychiatrists actually working on adolescent delinquency, the data and conceptions embodied in Sir Cyril Burt's *Young Delinquent* still hold the field, with little accession from more recent work; and it is no reflection on the merit of this pioneer study to wish for fuller confirmatory studies, based on wider data and other personal attitudes. The report on *Delinquency and Human Nature*,[1] compiled by Mr. D. H. Stott, M.A., is thus a particularly useful document. He presents clinical material of first-rate importance in a form which is generally comprehensible.

The basis is a detailed survey of 102 youths, between 15 and 18 years of age, in English approved schools. It was impossible to study persistent absconders, but otherwise there was no significant selection. Stott points out that the 15–18 age-group is of particular criminological interest: it is here that the greatest apparent numerical increase of offences has occurred in recent years; it provides the recruiting-ground for the persistent adult offender; and the cases in it have reached a stage, both in character-structure and in conflict with society, at which proper investigation is possible with a view to classifying the factors at work. The interview, the technique of which is described, was often supplemented by fairly extensive social contact and observation. To most readers, perhaps, the investigator's most notable comments are those on the factors which did *not* operate to produce delinquency. He points out that in none of the 102 cases studied did simple "wanting and taking" play any identifiable part. The cinema—where its influence was detectable—uniformly determined the type of crime, not its occurrence. Concerning "low moral standards" he aptly comments that since in almost all the boys delinquency constituted an outlet from an intolerable inner or outer environment, precisely because it was a disapproved and exceptional activity, low moral standards cannot be considered a primary factor: the child whose father is a burglar does not choose burglary as his own form of protest. "Lack of home discipline," which Stott investigated in some detail, he finds inseparable from a general inadequacy in the personality of the parent, and to this extent spoiling and harshness are opposite sides of the same coin.

He extracts five main motives behind delinquent action: avoidance-excitement (the excitement being a symptom of the unconscious avoidance—sometimes to the extent of complete amnesia or blackout—of a painful or distressing thought or memory), inferiority-compensation, delinquent-attention-seeking, resentment against parents, and desire for removal from home. Of these the first was by far the most conspicuous (53 cases) and desire for removal from home the most prevalent (58 cases). The cases are further cross-divided into categories of parental background. In all these groups, Stott repeatedly stresses the explosive nature of crime, its function in relieving tensions in the criminal which are entirely unrelated to obvious motive and purposive wickedness, and the clear-cut distinction between the "once-er" who may benefit by reproof, and the persistent offender for whom reproof, punishment, and the reaction of society are part and parcel of the pattern which he deliberately courts when he adopts delinquency as an escape mechanism from inner forces. This is fully in line with widely diverse psychiatric experience, and is true of all persistent offences, from sadistic assault to pilfering. The offence is a breakdown, or more correctly a breaking out. In a few cases physical factors such as fright or illness

R. burneti has been demonstrated[15] with *Dermacentor andersoni*. It is tempting to argue that the tick is a primary and continuing reservoir of the infection in nature and that the disease can spread from it to various wild and domestic animals. The ticks and animals involved seem to differ according to the locality. Cows, sheep, and goats have been found to be infected in nature, and other domestic animals such as the horse, mule, and dog are experimentally susceptible. The disease may be spread among the domestic animals by the appropriate tick, but in California, at least, this does not seem to be so. Other blood-sucking insects might repay investigation, but it seems likely that *R. burneti* has sometimes become independent of arthropods and that its successful colonisation of the mammary gland and possibly the genital tract[16] will at any rate partly explain its spread among these animals. Infected dust and milk may be the intermediate links in the chain, as they are in the spread of infection from animal to man.

Epidemiological investigations of Q fever in Great Britain are at an early stage. The identification of cases by Stoker[17] and the description of an outbreak by Harman[18] and MacCallum et al.[19] last year has been followed by the discovery of other sporadic cases. Most of these have been found in south-east and south-west England, though a few have been recognised elsewhere. Serological evidence of infection of cattle has been established, and *R. burneti* has been isolated from milk in the areas where cases have occurred. The present aims of the investigators are to define the endemic areas by serological surveys of the human and bovine populations, and to study the incidence of the disease in man, animals, and arthropods in two small endemic areas.

Towards Control of Hospital Expenditure?

To scouts reconnoitring towards an objective, the slow progress of the main army is often exasperating. The general waits first for this, then for that, and at last takes what seems a reluctant and inadequate step forward. So in the hospital world those who understand something of the history of hospital accounts and comparative statistics watch with something approaching resignation the slow motion of our new Leviathan in its efforts to establish controls. Besides issuing a "standstill" circular,[20] the Minister, as briefly noted last week, has announced three new steps. First, he is going to make mandatory a rather more detailed analysis of expenditure than that at present in use, in accordance with a scheme drawn up by the regional treasurers. We have not seen this form, but it seems from the context that it is on the old subjective lines, which, as we have urged before, ought scarcely to be described as "costing." Still the move is overdue, and we hope it will soon be followed by permission to publish the figures for the different hospitals. Secondly, the Minister is going to send out teams to fix establishments. This is surely a much more dubious proposition, for so much depends on who are chosen to compose the teams. If the task is passed to two or three of the best administrators in each region and they consult the right people, it may be done well enough and may serve a useful purpose; but if it is to be entrusted to men who lack first-class practical experience of running hospitals it may easily do more harm than good. Thirdly, the Minister has accepted a recommendation of the Central Health Services Council that King Edward's Hospital Fund for London and the Nuffield Provincial Hospitals Trust should be invited to undertake a costing investigation into a limited number of hospitals. That is to say, a definite attempt is to be made to try a true departmental system of hospital accountancy, whereby at long last valid comparisons between one hospital and another will become possible. This we have advocated more than once. The system to be adopted will no doubt be on the lines advocated by Captain J. E. Stone of the King's Fund in a series of articles we published last year; a somewhat similar system is understood to be in operation at the Radcliffe Infirmary under the auspices of the Nuffield Trust. This step will be widely welcomed, and most wholeheartedly by those who realise the bankruptcy of the present system of accounts. The King's Fund has long been a pioneer in hospital accountancy. It first established a measure of uniformity among the London voluntary hospitals many years ago, and its tables of comparative statistics have served well in their day. A departmental system thoroughly worked out and proved fit for general adoption may well mark a new era in hospital affairs.

The Secretary of State for Scotland has taken his own line, in a circular to hospital authorities and has suggested ways of ensuring economy. This circular is also in its way a step forward; unlike its English counterpart it attempts to educate its boards of management (= the hospital management committees of England and Wales) in the way they should set about control of expenditure. Thus the hospital authorities are urged to "compare ascertained costs as between hospitals and groups of hospitals, in total and under particular heads, and to arrange for the examination of all items which appear to be relatively high or to be increasing unduly. "Most Boards of Management," it is suggested, "can do much in this respect within their own groups"; and, it is indicated, "all will be able readily to obtain from the Regional Board comparative figures for hospitals more or less similar in type to their own." Moreover, "each Board of Management should also arrange to examine systematically, in turn, the main items in its expenditure—the numbers of junior medical, nursing, auxiliary and domestic staff, the cost of food for patients and staff, the consumption of fuel, power and light, laundry expenditure, and so on to satisfy itself as to the efficiency and economy of the existing practice." The fact that such advice should be thought necessary shows how far we have strayed (on both sides of the Border) from the older conception of hospital administration as the enlightened pursuit of economy. These techniques of comparing costs

Doubts on the mathematics of Rhine's experiments were expressed by one speaker: was it not possible, he asked, that some of the test results were due to a coincidence of a bias of the experimental subject with a bias of the material. Another speaker inquired where parapsychology ends and mysticism starts. Professor Rhine is confident that he is guided only by the logic of scientific procedure; and he is fully aware that he is working on dangerous ground. "This is a jungle. . . . We are frightened of the danger of making a false step."

YOUNG PEOPLE WORKING IN HOSPITALS

HOSPITAL cadet schemes and other unofficial pre-nursing courses designed to bridge the gap between school-leaving and admission of student nurses to training, are multiplying, with the result that more young girls between the ages of 15 and 18 are finding their way into the hospitals. In one way this is a good thing: an early wish to become a nurse is often lost in those intervening years, not because the enthusiasm is insincere or romantic but because it is never nourished. If the girl begins other work she often finds it inconvenient to change later; whereas if she can do work that has some links with nursing the training is progressive and the change-over natural.

Nevertheless, there are serious drawbacks to cadet schemes, as the Minister of Health fully recognises in a recent circular (R.H.B. [50] 37). He is anxious that the work assigned to young people should not be of a type for which they are unsuited by reason of their age, and that the conditions should be in keeping with the requirements of the Factories Acts and the Young Persons (Employment) Act. He has therefore drawn up some conditions of service appropriate to young people, and has set out types of work which are suitable and unsuitable for young people to undertake. These conditions are not laid down as regulations, anyhow for the present, but the Minister expects that hospital authorities will adopt them and put them into force as soon as possible.

He thinks that young people under 18 should not be allowed, in any hospital, to carry out any treatment or to have the care of drugs or to nurse sick people. They should not be employed in any capacity in operating-theatres or mortuaries, or in any way that would bring them into contact with the sick in homes for the dying, cancer hospitals, or venereal-disease hospitals or departments; or in the wards or attached to the wards of mental hospitals or mental-deficiency institutions. Nor should they be employed in the radiological, physical-medicine, or outpatient departments of mental hospitals, isolation hospitals, tuberculosis sanatoria, or in mental-deficiency institutions in any work which would bring them into contact with low-grade or difficult patients. For young people under the age of 17 he proposes some further restrictions: they should not be employed in the X-ray, physical-medicine, or outpatient departments of maternity hospitals, or in hospital reception rooms, or attached to wards in any type of hospital. This last provision is particularly sound, taking account as it does of the tuberculosis risk in general wards. The risks of acquiring infection from the known or suspected case hardly matter: they can be guarded against. The danger comes from the early unrecognised case of pulmonary tuberculosis with bacilli in the sputum. There are always some of these about, as mass radiography has shown, and adolescents should not deliberately be brought into contact with them. True, they will meet such unrecognised cases in buses and trains, but they do not as a rule undertake small personal services for their fellow travellers, or handle objects they have handled, or spend an hour or two within range of their coughing. At least one first-aid organisation outside the hospitals likes to send its cadets into the wards for a few hours each week: but much as the young people enjoy and appreciate the experience, they should not be granted it. The fact that most of them keep well should not weigh against the chance that here and there one may be infected with a serious disease.

The Minister's list of suitable duties for those between 15 and 18 includes work in diet kitchens, where the young people can help to prepare and serve diets and clean equipment; in X-ray departments, where they can help with filing, guide walking patients to other departments, look after linen, help in the dark-room, and play with waiting children; in the physical-medicine department, where they can look after the telephone, help to marshal waiting children, dust, clean equipment, and mend linen; in the outpatients, the almoner's department, the nurses home, and the linen room, where they can do comparable duties; in the records office, and the catering and steward's office, where they can help with clerical work. They can also act as messengers. Those between 17 and 18 can take on more responsible jobs, helping in the reception room by taking inquiries and messages, and learning the use of the switchboard; and on the wards, where they can share in the general care of the ward kitchens, bathroom, sluice room, sterilising-room and clinical room, clean equipment and cupboards other than the drug cupboard, help to cut up dressings and pack drums, help to serve meals, lay trays, arrange flowers, and do similar light tasks, all of which are specified in the memorandum.

The Minister further suggests that the maximum working hours (exclusive of meal and rest breaks) should be 44 hours a week for people under 16, and 48 for those of 16 and over, with a maximum of 9 hours in a day. An additional hour daily may be worked by those of 16 and over, provided that only 50 such hours are worked in a year, and that not more than 6 are worked in any week. The maximum span of work, he suggests, should be 11 hours, beginning not earlier than 7 A.M. and ending not later than 8 P.M. (6 P.M. for people under 16). The periods suggested for meal-breaks are 45 minutes for midday dinner and 30 minutes for tea. These hours, and particularly the span of work, seem to us too long. Night work is to be prohibited, and there must be a half-holiday and a full day off weekly. Public holidays, too, are to be allowed.

Hospital authorities should arrange for any young people who work for them to attend part-time courses for further education for the equivalent of one full day a week; and this must not be taken out of the time off duty. For those who intend to become nurses the further education course should be of a kind to fit them for their profession. The Ministry of Education will shortly be asking local education authorities to consider providing a new type of pre-nursing course, occupying one day a week for two years, designed to meet the needs of young people working in hospitals. The Minister asks hospital authorities to let the education authorities know what kind of courses they want, and to help the authorities in organising such courses by offering them accommodation and equipment and the services of lecturers on technical subjects.

ON May 8 the King visited Sir MORTON SMART in hospital and invested him with the insignia of the G.C.V.O.

THE next session of the General Medical Council will open on Tuesday, May 23, at 2 P.M., when Dr. DAVID CAMPBELL, the president, will deliver an address.

Prof. B. P. BABKIN, M.D., of McGill University, Montreal, who was elected F.R.S. earlier this year, died on May 3, at the age of 73.

determined the timing of a breakdown. With regard to war, Stott predicts from his data a fairly rapid decline in cases attributable to the actual events and conditions of war-time, though this forecast could not be taken to include cases due to the social and emotional factors on which war was engrafted, and which have in part persisted in the "cold" war. The average Raven test score for the group was 40, corresponding to the 36th percentile. Frank psychosis was not widespread, though some of the recorded cases show a curious pseudoschizophrenic reaction which is more familiar in older delinquents.

The most urgent problem in modern criminology is that of identifying the offender whose delinquency is compulsive *at his first offence*—that is, to pick out the recurring decimal. The anger of judges and moralists when the term "neurotic" is used in connection with delinquency cannot withstand the enormous body of evidence, both in this report and in general experience, which shows that while some crimes result from impulse or greed, the entire body of repeated and persistent crime arises as an inappropriate form of behaviour which gratifies an unconscious and irrational need in the criminal. This observation fits exactly into Horney's definition of a neurosis; over the wider issue, Stott remarks that "the moralist and the psychologist can eat grass together. In our present society we cannot afford the luxury of endlessly tolerating neurotic ways of life, delinquent or otherwise. . . . [But] the undiscriminating philosophy of a self determination has outgrown its usefulness when it insists on the ability of the psychopath to adjust himself unaided to life, and inflicts on him term after term of imprisonment in the vain hope that this will prove a deterrent."

At the present time a remarkable amount of ill-informed and ignorant comment on juvenile crime is being made by prominent people. It is important, therefore, that studies such as this—presented with humour and insight, from a wide general culture, and wholly free from emotional bias—should reach the general public. The Carnegie Foundation would do well to issue this report far outside its present envisaged circulation to libraries and interested individuals. It is a cheering document, and its title is well chosen, for it strengthens the humanist conviction that conduct is comprehensible even when it is not understood, and that we are within sight of an extension to human misconduct of the same epistemological and systematic method which has enabled us to control infectious disease. Mr. Stott is fully aware of these implications, and treats them at a level which will satisfy the philosopher as well as the psychiatrist. He deserves the support of all those, inside and outside psychiatry, who share his awareness.

PSI PHENOMENA AND PSYCHIATRY

Prof. J. B. Rhine, of Duke University, South Carolina, had a crowded audience of psychiatrists and psychologists when he lectured on parapsychology in the Royal Society of Medicine. Parapsychology, according to Rhine,[1] is the science of those mental manifestations that appear to transcend recognised principles. "It attempts to deal scientifically with the problem of man's place in nature and the relationship of the personality to the physical world." Professor Rhine credits Mesmer with having encountered and described both thought transference and clairvoyance. He referred to famous psychiatrists (Ribot, Janet, Freud, and others) who had reported examples of extrasensory perception. Interest in these phenomena has been growing among psychiatrists and psychologists of late, partly no doubt as the result of the work carried out in Professor Rhine's laboratory over the last twenty years. A recent inquiry among American psychiatrists revealed that, of 725 who replied, a quarter believed themselves to have encountered such phenomena, while 68% thought them worthy of investigation. The term "psi phenomena" was suggested by Thouless and Wiesner,[2] of Cambridge University. It is applied to both extrasensory perception, or E.S.P., (the extrasensory influence of mind on mind), and psychokinesis, or P.K. (the influence of mind on matter). Professor Rhine and others regard both as experimentally established beyond doubt, E.S.P. with the help of card tests, P.K. with dice tests. The technique of these methods and the application of the laws of chance in the interpretations of test results are described in Professor Rhine's books.

Their methods established, the investigators began to study the types of subjects and states of consciousness likely to produce demonstrable psi phenomena. Contrary to popular belief, they found no basic connection between mental abnormality, in the psychiatric sense, and psi phenomena; nor was there any indication that emotional maladjustment favoured their occurrence. They rather gained the impression that a high degree of emotional adjustment made for success in their tests, though a few of their media had been of an "excitable temperament." Hypnosis has been found to affect both P.K. and E.S.P., but controlled experiments have so far been inconclusive as to the kind of changes which these phenomena undergo in the hypnotic state. Psi phenomena are functions of the unconscious mind, and failure in experiments may be due to unconscious "negativism," resulting in large deviations which cannot be explained mathematically as chance effects. Rhine and his co-workers confirmed the observations made by Soal and Goldney[3] of the "displacement effect"—the extrasensory perception of objects near the target. The relation of psi phenomena to the functions of the nervous system is still unexplored, though a promising start has been made with tests in states following concussion. Urban,[4] of Innsbruck, using E.S.P. card tests before and after electroconvulsant treatment and narco-analysis, found a rise of the scores during a certain phase of clouding of consciousness; but his report is based on 100 tests only, and his experiments still require confirmation. Urban suggested that the emergence of psi phenomena was due to the removal of inhibiting mechanisms. Professor Rhine posed the question whether "there may not have been something in the mind that has been smothered in the history of evolution." He is inclined to regard the homing phenomena in animals as based on E.S.P., and referred to experiments which to him made this assumption almost inescapable. The "vestigial theory" of the psi phenomena has many adherents among parapyschologists. Professor Rhine regards these phenomena as a challenge to our psychological and philosophical concepts: do they not force us back from our unitary concept of the mind-body relationship, he asks, to a dualistic conception of man? We must choose between a mind-centred (psychocentric) and a brain-centred (cerebrocentric) conception. Although he owned to being cautious and open to correction, he left no doubt where his sympathies lay, and he was supported by Mr. Thouless who also felt that parapyschology seemed to be pointing to the old idea that soul ruled the body. According to present-day psychological theory, psi phenomena should not take place; but they do. Psychological theories, Mr. Thouless said, must take account of parapsychological facts.[5] Other speakers reported on psi phenomena from their own experience.

Doubts on the mathematics of Rhine's experiments were expressed by one speaker: was it not possible, he asked, that some of the test results were due to a coincidence of a bias of the experimental subject with a bias of the material. Another speaker inquired where parapsychology ends and mysticism starts. Professor Rhine is confident that he is guided only by the logic of scientific procedure; and he is fully aware that he is working on dangerous ground. "This is a jungle. . . . We are frightened of the danger of making a false step."

YOUNG PEOPLE WORKING IN HOSPITALS

HOSPITAL cadet schemes and other unofficial pre-nursing courses designed to bridge the gap between school-leaving and admission of student nurses to training, are multiplying, with the result that more young girls between the ages of 15 and 18 are finding their way into the hospitals. In one way this is a good thing: an early wish to become a nurse is often lost in those intervening years, not because the enthusiasm is insincere or romantic but because it is never nourished. If the girl begins other work she often finds it inconvenient to change later; whereas if she can do work that has some links with nursing the training is progressive and the change-over natural.

Nevertheless, there are serious drawbacks to cadet schemes, as the Minister of Health fully recognises in a recent circular (R.H.B. [50] 37). He is anxious that the work assigned to young people should not be of a type for which they are unsuited by reason of their age, and that the conditions should be in keeping with the requirements of the Factories Acts and the Young Persons (Employment) Act. He has therefore drawn up some conditions of service appropriate to young people, and has set out types of work which are suitable and unsuitable for young people to undertake. These conditions are not laid down as regulations, anyhow for the present, but the Minister expects that hospital authorities will adopt them and put them into force as soon as possible.

He thinks that young people under 18 should not be allowed, in any hospital, to carry out any treatment or to have the care of drugs or to nurse sick people. They should not be employed in any capacity in operating-theatres or mortuaries, or in any way that would bring them into contact with the sick in homes for the dying, cancer hospitals, or venereal-disease hospitals or departments; or in the wards or attached to the wards of mental hospitals or mental-deficiency institutions. Nor should they be employed in the radiological, physical-medicine, or outpatient departments of mental hospitals, isolation hospitals, tuberculosis sanatoria, or in mental-deficiency institutions in any work which would bring them into contact with low-grade or difficult patients. For young people under the age of 17 he proposes some further restrictions: they should not be employed in the X-ray, physical-medicine, or outpatient departments of maternity hospitals, or in hospital reception rooms, or attached to wards in any type of hospital. This last provision is particularly sound, taking account as it does of the tuberculosis risk in general wards. The risks of acquiring infection from the known or suspected case hardly matter: they can be guarded against. The danger comes from the early unrecognised case of pulmonary tuberculosis with bacilli in the sputum. There are always some of these about, as mass radiography has shown, and adolescents should not deliberately be brought into contact with them. True, they will meet such unrecognised cases in buses and trains, but they do not as a rule undertake small personal services for their fellow travellers, or handle objects they have handled, or spend an hour or two within range of their coughing. At least one first-aid organisation outside the hospitals likes to send its cadets into the wards for a few hours each week: but much as the young people enjoy and appreciate the experience, they should not be granted it. The fact that most of them keep well should not weigh against the chance that here and there one may be infected with a serious disease.

The Minister's list of suitable duties for those between 15 and 18 includes work in diet kitchens, where the young people can help to prepare and serve diets and clean equipment; in X-ray departments, where they can help with filing, guide walking patients to other departments, look after linen, help in the dark-room, and play with waiting children; in the physical-medicine department, where they can look after the telephone, help to marshal waiting children, dust, clean equipment, and mend linen; in the outpatients, the almoner's department, the nurses home, and the linen room, where they can do comparable duties; in the records office, and the catering and steward's office, where they can help with clerical work. They can also act as messengers. Those between 17 and 18 can take on more responsible jobs, helping in the reception room by taking inquiries and messages, and learning the use of the switchboard; and on the wards, where they can share in the general care of the ward kitchens, bathroom, sluice room, sterilising-room and clinical room, clean equipment and cupboards other than the drug cupboard, help to cut up dressings and pack drums, help to serve meals, lay trays, arrange flowers, and do similar light tasks, all of which are specified in the memorandum.

The Minister further suggests that the maximum working hours (exclusive of meal and rest breaks) should be 44 hours a week for people under 16, and 48 for those of 16 and over, with a maximum of 9 hours in a day. An additional hour daily may be worked by those of 16 and over, provided that only 50 such hours are worked in a year, and that not more than 6 are worked in any week. The maximum span of work, he suggests, should be 11 hours, beginning not earlier than 7 A.M. and ending not later than 8 P.M. (6 P.M. for people under 16). The periods suggested for meal-breaks are 45 minutes for midday dinner and 30 minutes for tea. These hours, and particularly the span of work, seem to us too long. Night work is to be prohibited, and there must be a half-holiday and a full day off weekly. Public holidays, too, are to be allowed.

Hospital authorities should arrange for any young people who work for them to attend part-time courses for further education for the equivalent of one full day a week; and this must not be taken out of the time off duty. For those who intend to become nurses the further education course should be of a kind to fit them for their profession. The Ministry of Education will shortly be asking local education authorities to consider providing a new type of pre-nursing course, occupying one day a week for two years, designed to meet the needs of young people working in hospitals. The Minister asks hospital authorities to let the education authorities know what kind of courses they want, and to help the authorities in organising such courses by offering them accommodation and equipment and the services of lecturers on technical subjects.

THE REGISTRAR SYSTEM IN NON-TEACHING HOSPITALS

D. Vellacott
M.B. Camb., F.R.C.S.
A SENIOR REGISTRAR

For most provincial non-teaching hospitals the registrar system is a comparatively recent innovation. Senior registrars or their equivalents—first assistants—have for many years been a feature of teaching hospitals, where their position and duties have been fairly clearly defined, with minor variations between different schools. Their duties usually consist of emergency and routine surgery at the discretion of the " chief," certain duties in outpatient clinics, the teaching of students, and responsibility for the documentation and recording of cases. Research is usually voluntary, although sometimes suggested and directed by the chief. Teaching hospitals are to some extent the " shop-window " of medicine and surgery, and as training centres they are justifiably regarded with great respect, credit accruing to the registrars fortunate enough to hold appointments there.

In the career of the would-be consultant a registrarship is a crucial stage, for it offers him an opportunity to form, in the light of practical experience, fundamental principles for the future ; to benefit from the experience, direction, and criticism of senior staff engaged in the same problems that he has to face ; and to make good himself.

CRITERIA

What are the particular facilities in teaching hospitals which help the would-be consultant ? Briefly, they seem to be these : (1) Working with, and learning from, men eminent in the profession ; (2) practical experience ; (3) the teaching of students, which forces the registrar to clarify his own ideas ; (4) practical work, during a formative period, in a school ; (5) opportunities for attending lectures and meetings in, or near, the teaching centre, and readily available libraries and museums ; (6) opportunities for research and controlled investigations, with first-class ancillary services ; (7) facilities and accommodation for learning and practising the proper recording of cases ; and (8) contact with the basic medical sciences of anatomy, physiology, and pathology.

If these criteria are accepted, how does the position of a registrar in a non-teaching hospital compare with that of his colleague in a teaching hospital ? As regards the men under whom he works, he may not be at a disadvantage, except that his chief may not be interested in, or accustomed to, teaching ; and for practical experience and clinical material, the non-teaching may surpass the teaching hospital. In the remaining six points, however, the registrar at a non-teaching hospital is often at a disadvantage. Furthermore, he is liable to become so involved in practical work, and problems arising from shortage of beds, as to lose sight of the ideal management of a case. He may receive a fine training in life-saving, but his work is necessarily directed to keeping patients out of hospital rather than to selecting patients for admission, and surgery that is economically important is in danger of being neglected. Moreover, outpatient clinics may be so large that history-taking and clinical examination are curtailed, and investigation by ancillary services substituted.

Speaking of surgery, one cannot fail to notice that super-specialised units often appear to gain certain advantages over general units. The former seem to catch the sympathetic eye of the public, of committees, and lay members of staffs, obtaining better ancillary services (including their own physiotherapists) and full clerical assistance. The stomach is removed by either a thoracic or a general surgeon ; but the team-work supporting the former is not always as good for the latter. It seems that undue importance may come to be attached to registrar service on a specialised unit, so that a succession of appointments to such units may become necessary to obtain a recognised general surgical training. General surgery deserves clearer recognition as a basic training for would-be consultants ; and support for general units should equal that for special units. It may, of course, be pointed out that general surgeons often have a particular interest in one branch ; and certainly a system of rotation of registrars does much to ensure a balanced training.

House-appointments should provide a general training for the recently qualified doctor. In this respect the non-teaching hospitals have in the past rivalled the teaching hospitals, residents obtaining practical experience from large and varied clinical material, together with greater responsibility than is usually allowed in teaching hospitals. Does not the adoption of the registrar system endanger the value of these appointments ?

After holding a house-appointment, the decision has to be made whether to go into general practice or to try to become a consultant. If the latter course is chosen, a registrarship should be a definite rung on the ladder, with prospects of advancement, and encouragement to study. The non-teaching hospitals could, and should, provide training and prospects rivalling those in teaching hospitals ; otherwise registrars working in non-teaching hospitals will find themselves at a disadvantage in the competition for consultant posts.

PROPOSALS

The following measures would, it is suggested, improve the value of registrar posts in the non-teaching hospitals, and benefit the hospitals themselves :

House-appointments.—The house-surgeon (or house-physician) should be primarily responsible to the consultant for the management of cases in the wards, taking the chief round and answering questions about the cases, dealing with most of the details of investigation and treatment, and recording history, examination, investigations, operations, and progress of each case. Naturally the registrar should, if required, answer for cases which he has himself dealt with.

The registrar should be concerned more with the management of the ward itself, seeing that the consultant's particular wishes and methods of management are carried out, that records are properly kept, and that new housemen are helped over the initial period of six weeks or so until they understand the routine of the wards and have mastered such procedures as putting up a transfusion and passing catheters.

Facilities for the registrar.—It should be part of the duties of a registrar to summarise and analyse case-notes, not only for purposes of recording, but for his own instruction and training ; in this he should be able to work in conjunction with the records department and render considerable assistance. He may be required, by some consultants, to write letters to the patients' doctors. If this work is to be done efficiently, there must be a separate room for registrars, where they will be free from constant interruptions. Clerical assistance is likewise essential. Provision of these two essentials would instantly raise the standard of notes and outpatient records ; ensure a speedier and more efficient contact with general practitioners ; and diminish the number of " forgotten " patients. But, for the registrars, a separate room and clerical assistance would do much more : it would provide a stimulus to reading and study, and analysis of cases. I have no doubt that registrars themselves would provide medical journals ; and in this local medical societies are already of great assistance.

Emergency and routine surgery.—Emergency surgery is good training—for emergency surgery. It would be a pity if registrars were employed only in this type of work; and registrars—or at least senior registrars—might be allotted one operating session a week.

Meetings and lectures.—In each hospital one registrar should be selected each month to attend a meeting on a subject of his choice, at one of the Royal Colleges, the Royal Society of Medicine, or a teaching hospital, with the obligation to report the proceedings, either verbally or in writing, to his consultants on his return; and a pool of money should be provided by regional boards to cover expenses where long distances are involved. The granting of opportunities to go on courses, after a certain period of service, might be considered. The recognition of some such system as a privilege of a post in a non-teaching hospital would do much to allay the fears of registrars who consider applying for posts remote from teaching centres.

Research.—It is in research that the registrar in the non-teaching hospital finds himself most frustrated. Often masses of clinical material pass before his eyes and stimulate his interest, but the difficulties already enumerated, and the involvement of himself and the ancillary departments in practical work, prevent him from pursuing lines of investigation with proper support. Registrars (if necessary, only the higher grades) should be allowed investigations not vitally essential, and in these the pathological registrar should assist as a part of his duties. Access to post-mortem examinations, opportunities to try operations on the cadaver, and, in interesting cases, the provision of microscopic slides, should be assured.

ASSESSING STANDARDS

Finally it is suggested that the Royal Colleges, or the regional boards, should take some part in ensuring that registrar appointments conform to certain training standards. A system of hospital standardisation, as employed by the American College of Surgeons, has much to commend it. If I may quote[1]:

> "Medical records departments play an essential part—as indeed they must do if the hospital concerned is to gain the approval of the American College of Surgeons—a standard of merit which all hospitals in the U.S.A. covet and endeavour to obtain. It is termed Hospital Standardization, and it is possible to score 1000 marks. The scoring sheet is divided into eight essential divisions, total score 655 marks, and ten adjunct and service divisions, total score 345. It is significant that the medical record department is allocated to the essential divisions, with the second highest possible score of 150 points, 250 out of the 655 points being allocated to the medical staff organisation. Clinical laboratory comes third in that division with 95 points."

Some such system would also give candidates for registrar posts some idea of the value of appointments before they actually took them up, and would stimulate competition and rivalry between hospitals.

I would ask senior consultants to compare the prospects which consultant practice offers today with those they faced some years ago—prospects, not conditions. It is doubtful whether prospect of financial gain will ever again be the same spur to greater effort. In medicine and surgery we have a profession where opportunities for healthy unselfish enterprise abound. It seems obvious that gratification and fulfilment will have to be derived from the very nature of the work. If standards in medicine and surgery are not to fall, senior members of hospital staffs will have to do all in their power to arouse enthusiasm and encourage capacity for criticism.

Obviously, the views expressed here have been formed as a result of experience in a particular hospital; but they may have a wider application. They are frankly expressed because the almost universal adoption of the registrar system calls for a recognised standard of training facilities, and presents a challenge which all non-teaching hospitals should recognise.

---

EMERGENCY BED SERVICE

LAST autumn branch offices of the King Edward's Hospital Fund Emergency Bed Service were opened at Ealing, Leytonstone, Woolwich, and Wimbledon to carry part of the load which had previously been borne entirely by the head office at Old Jewry. The branch offices now deal with 42% of the applications received. The committee's report on last year's working of the service relates how, through this decentralisation, the speed of admission and the proportion of admissions have both been increased though the total number of applications has risen steeply.

Since the introduction of the National Health Service the E.B.S. has been working for the four Metropolitan regional hospital boards for an experimental period of two years. The experiment has proved useful, and a new agreement has been reached whereby the E.B.S. is to carry on for a further two years and thereafter indefinitely, subject to six months' notice by either party. The King's Fund will continue to pay the first £6500, which was the cost of the E.B.S. in 1947, and the four boards share any expenses in excess of that sum.

THE YEAR'S WORKING IN LONDON

The total number of applications received during the year ended March 31, 1950, was as follows:

General acute cases	42,732
Infectious cases	14,506
Chronic sick cases	3411
Total number of cases ..	60,649

Of the 42,732 general cases offered, 34,575 were admitted, and 2488 withdrawn by the applicant. For the remaining 5669 no beds could be found, and they were referred back to the applicant. In 1070 of these cases the applicant was a hospital, and the patient was in the casualty department, but could not be admitted to the wards owing to their lack of beds.

Comparison of the winter results for 1948–49 and 1949–50 shows that the number of cases admitted, shown as a percentage of cases offered, was 73·5% and 78·5% respectively. The worst months in each winter were 75% in January and February, 1950, and 60% in February, 1949.

During last winter there was once again difficulty in admitting patients over 60 years of age, although the situation has improved since the first winter of the N.H.S. Nearly all age-groups show improvement over last year, the greatest being in the age-group 51–60 where the percentage admitted increased by 8·1. The exception is in the age-group 0–21 which shows a reduction of 0·4%, largely owing to the number of cases of bronchopneumonia in children which it proved impossible to admit during January.

In the winter of 1948–49 the average time taken to admit a case was 56 minutes. Last winter it was reduced to 42 minutes; to find a bed an average of 3·36 hospitals was approached in each case compared with 3·64 in the winter of 1948–49. During that winter, when the E.B.S. failed to find a bed for a patient, 5·15 hospitals were tried. This year an average of 7·05 hospitals were approached before failure was admitted.

The system of dealing with applications for inclusion on chronic sick waiting-lists was revised in November, 1949, when the records of these cases were transferred to the four branch offices which became responsible for the allocation of cases to the waiting-list of the appropriate hospital management committee. This work is done under the direct supervision of the regional medical admissions officers, who check that the case is suitable for a waiting-list, and take steps to obtain a report on the social circumstances where necessary. The new machinery is working satisfactorily, but it is obvious that the hospital management committees will continue to experience great difficulties in regard to these cases so long as the facilities for dealing with the chronic sick remain so inadequate. Until the situation improves it is difficult to see how waiting-lists can be materially reduced.

Since the winter of 1948–49 all patients for whom the E.B.S. is unable to find a bed are referred to the regional medical admissions officers. Formerly these officers referred the case back to the general practitioner, or themselves telephoned a regional board hospital and required it to accept the case. In January, 1949, hospital management committees in the four regions were asked by the regional boards to appoint a senior hospital officer in their group to whom the R.M.A.O. could refer an urgent case, and who would be responsible for finding a bed in the group, or for making certain that no bed was available. Since their appointment 1005 cases have been referred to the group medical referees. In many cases the medical referee has discussed the case with the general practitioner and been able to arrange either for admission within the next day or two, or for a domiciliary visit by a consultant.

IN THE PROVINCES

There are also branches of the service at Chelmsford, Watford, Brighton, and Tunbridge Wells, which are managed by the service, and the cost is a direct charge to the boards concerned.

The *Chelmsford office*, which serves the whole of the county of Essex outside the Metropolitan police district, dealt with 3129 applications for admission last year. It also arranges maternity bookings for the Chelmsford group H.M.C., and helps with the admission of patients to convalescent homes.

The *Watford office*, which covers the area served by the West Herts, Mid Herts, Barnet, and Harefield and Northwood hospital management committees, dealt with 2254 applications for admission. It also maintains waiting-lists of chronic sick cases on behalf of the management committees.

The *Brighton office* covers the area of the Brighton and Lewes group hospital management committee. It dealt with 3043 applications for admission.

The *Tunbridge Wells office* dealt with 1241 applications for admission. It also deals with maternity bookings, and it is often used by doctors as an information bureau. The group chronic sick waiting-list is kept in the office. All cases received from general practitioners are referred to the group geriatrician, who visits the patients and informs the Tunbridge Wells office of his findings.

LONDON TEACHING HOSPITALS

BOARDS OF GOVERNORS

THE Minister of Health has made the following appointments, mainly to fill vacancies caused by the retirement of a third of the members, to the boards of governors of the 26 London teaching hospitals. Of 207 appointments, 169 are reappointments of retiring members. There are 5 appointments outstanding. The names of the medical profession are shown in bold type.

ROYAL HOSPITAL OF ST. BARTHOLOMEW

Reappointed : Sir Herbert Cohen, O.B.E. ; Sir **Henry Dale**, O.M., G.B.E., F.R.C.P., F.R.S. ; Prof. H. G. Jackson ; E. T. Neathercoat, C.B.E., J.P. ; A. McL. Niven, J.P. ; R. R. J. Turner, O.B.E. ; J. S. Weatherley.

New members : **E. R. Cullinan**, F.R.C.P. ; **O. S. Tubbs**, F.R.C.S.

LONDON HOSPITAL

Reappointed : Horace Denton ; Prof. B. Ifor Evans ; Miss Elizabeth Farrelly ; **D. W. C. Northfield**, F.R.C.S. ; V. C. Ponsonby, M.C. ; W. M. Pryor, D.S.O.

New members : Mrs. R. C. Littlejohn ; C. S. B. Wentworth-Stanley ; **Hermon Taylor**, F.R.C.S.

ROYAL FREE HOSPITAL

Reappointed . Alderman Mrs. Martin Smith, M.B.E. ; **Clifford Morson**, O.B.E., F.R.C.S. ; Prof. **Mary F. Lucas Keene**, M.B. ; Prof. T. S. Moore ; **J. D. McLaggan**, F.R.C.S. ; Prof. Winifred Cullis, C.B.E. ; W. E. Ford.

New member : A. H. Telling.

UNIVERSITY COLLEGE HOSPITAL

Reappointed : Prof. **S. J. Cowell**, F.R.C.P. ; D. R. Pye, C.B.E. ; **M. L. Formby**, F.R.C.S. ; A. Shefford, O.B.E. ; **E. A. Gregg**, L.R.C.P.I., J.P.

New members : Mrs. Margaret Harvey, J.P. ; Mrs. I. M. Bolton ; Sir Cosmo Parkinson, G.C.M.G., K.C.B., O.B.E.

MIDDLESEX HOSPITAL

Reappointed : Fred Messer, C.B.E., M.P., J.P. ; Simon Whitbread ; W. B. Morrison ; **M. H. Whiting**, O.B.E., F.R.C.S. ; Prof. **B. W. Windeyer**, F.F.R. ; Sir Eric Gore-Browne, D.S.O ; L. F. Heald, K.C., M.P. ; C. G. Izard, O.B.E.

New member : Reginald Pestell, D.ECON., J.P.

CHARING CROSS HOSPITAL

Reappointed : H. E. Comben, A.M.I.C.E. ; Sir John Stewart-Wallace, C.B. ; **W. D. Southern**, M.R.C.S., L.D.S. ; David Trevor ; Mrs. Elsie O. Lindgren ; H. P. Marshall ; Hon. Mr. Justice Morris ; G. A. Pargiter, M.P.

New member : Mrs. Ann Blofield.

ST. GEORGE'S HOSPITAL

Reappointed : J. B. Bennie, J.P. ; Hon. Mrs. Reginald Coke ; E. O. Durlacher ; Mrs. Helga Feiling ; W. D. Little ; Sir Hugh Lucas-Tooth, M.P. ; **M. F. Nicholls**, F.R.C.S. ; **C. P. Pinckney**, F.R.C.P. ; R. H. Pott.

New members : Hon. **G. J. U. Bridgman**, F.R.C.S. ; I. F Salmon (until March 31, 1951).

WESTMINSTER HOSPITAL

Reappointed : A. N. H. Baines ; Sir Frederick Bovenschen, K.C.B., K.B.E. ; **C. J. Gavey**, F.R.C.P. ; Mrs. R. Margeurite High ; **T. J. Millin**, F.R.C.S. ; **P. H. Mitchiner**, C.B., C.B.E., F.R.C.S., Sir Harry Vanderpant.

New members : Hon. Christopher Addison : H. Solomon ; Alderman Miss E. McCullough.

ST. MARY'S HOSPITAL

Reappointed : Sir **Alexander Fleming**, F.R.C.P., F.R.S. ; Miss **Esther Rickards**, F.R.C.S. ; Lord McGowan, K.B.E. ; Prof. **Wilfred D. Newcomb**, F.R.C.P. ; **Richard Doll**, M.D., F.R.C.P. ; I. M. Gluckstein ; A. H. Lee ; Lady Plummer, H. L. Smedley.

New member : **W. D. W. Brooks**, F.R.C.P.

GUY'S HOSPITAL

Reappointed : S. B. Askew ; Alderman R. H. Burslem, J.P. ; E. V. Evans, O.B.E. ; *Prof.* **T. B. Johnston**, C.B.E., M.D. ; K. I. Julian ; Henry Levitt ; Prof. **W. R. Spurrell**, F.R.C.S., **F. S. Warner**, M.R.C.S., F.D.S.

New members : W. J. Driscoll ; Miss Mabel Crout.

KING'S COLLEGE HOSPITAL

Reappointed : Ralph Cocker ; **Terence East**, F.R.C.P., G. Hart ; H. L. Kendell ; Hon. Mrs. Charles Tufton, O.B.E.

New members : W. Trott ; **Sidney Thompson**, F.R.C.P. ; T. S. Stigger ; **Louis Minski**, F.R.C.P.

ST. THOMAS'S HOSPITAL

Reappointed : **G. H. Bateman**, F.R.C.S. ; **J. Bishop Harman**, F.R.C.P. ; R. J. Sainsbury ; Mrs. Doris A. *Thomas* ; **N. E. Waterfield**, F.R.C.S. ; S. W. Whiffen ; **J. M. Wyatt**, F.R.C.O.G. ; C. R. N. Winn, C.B., O.B.E., LL.M.

New members : Sir Herbert Thompson, C.I.E. ; Mrs. G. L. Rogers.

HAMMERSMITH, WEST LONDON AND ST. MARK'S HOSPITALS

Reappointed : E. G. Anthony, B.E.M. ; *Prof.* **Ian Aird**, F.R.C.S. ; Dame Katherine Jones ; **Horace Joules**, F.R.C.P. ; Prof. E. J. King, D.SC. ; **O. V. Lloyd-Davies**, F.R.C.S. ; Miss Amy Sayle, M.B.E. ; Mrs. M. Griffiths.

New member : J. B. Bennie, J.P.

HOSPITAL FOR SICK CHILDREN

Reappointed : **W. C. V. Brothwood**, M.D. ; Mrs. B. A. Beaumont, J.P. ; Miss E. V. Eckhard ; **G. H. Macnab**, F.R.C.S. ; Hon. Margaret Bigge ; Lady Thomas ; Theodore Magnus Wechsler, M.B.E. ; **I. A. B. Cathie**, M.D.

NATIONAL HOSPITAL FOR NERVOUS DISEASES

Reappointed : **J. B. Hunter,** C.B.E., M.C., F.R.C.S. ; Hon. Mrs. Richard Lyttleton ; **MacDonald Critchley,** F.R.C.P. ; Countess of Rothes ; W. H. Taylor.

New members : Mrs. B. Drake ; Sir Norman Strathie, K.C.I.E.

ROYAL NATIONAL THROAT, NOSE AND EAR HOSPITAL

Reappointed : Mrs. Doris E. Clark ; Lewis-Davis Lewis ; Prof. **F. C. Ormerod,** F.R.C.S. ; A. G. Farr ; J. R. Rosselli ; Mrs. Arthur Rye.

New member : Mrs. Frances Timpson (until March, 31, 1952).

MOORFIELDS, WESTMINSTER AND CENTRAL EYE HOSPITAL

Reappointed : N. E. Behrens ; **J. D. M. Cardell,** F.R.C.S. ; **N. McDiarmid,** M.B. ; **F. W. Law,** F.R.C.S. ; Bryan Roberts ; Miss Spencer-Wilkinson ; Sir John Stainton, K.B.E., K.C.

New member : A. P. V. Smyth.

BETHLEM AND MAUDSLEY HOSPITALS

Reappointed : W. J. Bourne ; Alderman Sir Frederick Wells ; Alderman E. V. M. Stockdale ; Prof. **A. J. Lewis,** F.R.C.P. ; **T. A. Munro,** M.D.

New members : Prof. **Alfred Meyer,** M.D. ; Colonel R. M. Rendel ; Anthony Greenwood, M.P.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN

Reappointed : **G. M. Frizelle,** M.D. ; Sir **Archibald Gray,** C.B.E., F.R.C.P. ; **F. Ray Bettley,** F.R.C.P. ; Hal Gutteridge ; Humphrey Whitbread.

HOSPITALS FOR DISEASES OF THE CHEST

Reappointed : Mrs. M. G. Burton ; J. H. Cooke ; **A. Hope Gosse,** F.R.C.P. ; Sir **Bennett Hance,** K.C.I.E., O.B.E., M.D. ; A. J. Newman ; Mrs. M. Omerod ; Sir Hugh Turnbull, K.C.V.O., K.B.E. ; **F. H. Young,** O.B.E., F.R.C.P.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL

Reappointed : A. E. Renenson Coucher, F.R.I.C.S., J.P. ; **A. T. Fripp,** F.R.C.S. ; **H. J. Seddon,** F.R.C.S. ; Sir Howard Kerr, K.C.V.O., C.M.G., O.B.E. ; William Nicholls, J.P. ; Miss Grace Rattenbury.

NATIONAL HEART HOSPITAL

Reappointed : **R. C. Brock,** F.R.C.S. ; **J. M. H. Campbell,** O.B.E., F.R.C.P. ; J. Simons ; L. H. Watts.

New member : Mrs. E. V. Whiter.

ST. PETER'S AND ST. PAUL'S HOSPITALS

Reappointed : H. Lythgoe ; **A. W. Badenoch,** F.R.C.S. ; **R. Ogier Ward,** D.S.O., O.B.E., M.C., F.R.C.S. ; **J. E. Semple,** F.R.C.S. ; Colonel A. R. Martin ; Sir Hewitt Skinner ; H. M. Tobin.

ROYAL CANCER HOSPITAL

Reappointed : **A. Lawrence Abel,** F.R.C.S. ; D. Jackman, M.B.E. ; D. E. W. Gibb ; W. G. Wilsher ; F. Griffiths Woollard, J.P.

New member : Councillor Douglas Clark.

QUEEN CHARLOTTE'S AND CHELSEA HOSPITALS

Reappointed : **Frank Cook,** F.R.C.S. ; Hon. Mrs. Eliot Hodgkin ; **J. Montagu Wyatt,** F.R.C.O.G. ; Prof. **James Young,** D.S.O., F.R.C.O.G.

New members : Mrs. P. Burton ; L. F. Ramseyer, D.S.O. ; Mrs. T. Keep.

EASTMAN DENTAL HOSPITAL

Reappointed : Sir Percy Everett ; Prof. **W. E. Herbert,** M.R.C.S. ; **C. F. Ballard,** M.R.C.S., L.D.S. ; Miss E. N. Morton.

Public Health

PUBLIC-HEALTH ENGINEERING

THIS country has a long and fine tradition of environmental sanitation, which was the foundation of its public-health service. One of the pioneers in training sanitary officers for their duties was the Royal Sanitary Institute, founded in 1876 ; the following year the institute entered the educational field and set up its first board of examiners. The examinations were designed for local surveyors and inspectors of nuisances and the candidates were expected to reach a standard of competence in "preventive medicine, chemistry, engineering and sanitary jurisprudence." The first examination was held on Oct. 29, 1877, and a distinguished group of examiners, including medical scientists, engineers, and architects, passed five students out of eight entrants. The sanitary inspector of today receives a comprehensive training on lines laid down by the Royal Sanitary Institute and is recognised by law and custom as a guardian of the public health.

There was a time when a sanitary inspector could undertake almost all the environmental work of the health department, even in a large and densely populated area. From the beginning of the present century, however, enormous technical advances have been taking place especially in sanitary engineering, housing, and town planning ; the sphere of the sanitary inspector, like that of the medical officer of health, has become narrowed by specialism within the group, but without sacrificing its fundamental importance to the protection of the community. During the past generation it has been demonstrated in the United States and elsewhere, that there is a special need for public-health engineering in the modern community. For many years this has been recognised as a fact in modern communities and many of our more populous areas have large progressive engineering departments controlling most of the essential services such as water-supply, sewerage, sewage disposal, public cleansing, and works of many kinds that the modern city requires. In the United States this change has been recognised by the establishment of special postgraduate courses for engineers, designed to give them a fuller understanding of the principles of public health in relation to their profession. Experience there has shown that the postgraduate study of public-health engineering is best organised as a joint venture between the university schools of engineering and their postgraduate departments of public health. In this way the engineer receives instruction side by side with those with whom he has to work in the field—health officers and public-health nurses. The day-to-day contact established between these officers, and the give and take of their discussion in seminars and practical district work, is of great value in enabling them to understand one another's point of view. It is, of course, important to realise that the doctor and the nurse gain quite as much as the engineer from the joint instruction.

A NEW ENTERPRISE

Postgraduate courses in public-health engineering are now well established in the United States and are closely linked with public-health teaching. The Rockefeller Foundation is giving its encouragement and support to a scheme of this kind in Great Britain. The Imperial College of Science and Technology and the London School of Hygiene and Tropical Medicine have been chosen for this experiment, and the joint enterprise which they are beginning in the autumn of this year is supported by eminent engineers and medical men. A Public Health Engineering Advisory Committee has been established by the governing body of Imperial College to assist in policy and organisation. On this advisory committee are represented the senate of the University of London, the London School of Hygiene and Tropical Medicine, the Institution of Sanitary Engineers, the Royal Sanitary Institute, and the Society of Medical Officers of Health.

The course in public-health engineering, to be carried out principally at Imperial College, is intended for graduate engineers and covers one academic year. The plan of the proposed course has now been worked out in detail. The studies fall naturally into three groups. First come the basic sciences of mathematics, physics, management committees will continue to experience great difficulties in regard to these cases so long as the facilities for dealing with the chronic sick remain so inadequate. Until the situation improves it is difficult to see how waiting-lists can be materially reduced.

Since the winter of 1948–49 all patients for whom the E.B.S. is unable to find a bed are referred to the regional medical admissions officers. Formerly these officers referred the case back to the general practitioner, or themselves telephoned a regional board hospital and required it to accept the case. In January, 1949, hospital management committees in the four regions were asked by the regional boards to appoint a senior hospital officer in their group to whom the R.M.A.O. could refer an urgent case, and who would be responsible for finding a bed in the group, or for making certain that no bed was available. Since their appointment 1005 cases have been referred to the group medical referees. In many cases the medical referee has discussed the case with the general practitioner and been able to arrange either for admission within the next day or two, or for a domiciliary visit by a consultant.

IN THE PROVINCES

There are also branches of the service at Chelmsford, Watford, Brighton, and Tunbridge Wells, which are managed by the service, and the cost is a direct charge to the boards concerned.

The *Chelmsford office*, which serves the whole of the county of Essex outside the Metropolitan police district, dealt with 3129 applications for admission last year. It also arranges maternity bookings for the Chelmsford group H.M.C., and helps with the admission of patients to convalescent homes.

The *Watford office*, which covers the area served by the West Herts, Mid Herts, Barnet, and Harefield and Northwood hospital management committees, dealt with 2254 applications for admission. It also maintains waiting-lists of chronic sick cases on behalf of the management committees.

The *Brighton office* covers the area of the Brighton and Lewes group hospital management committee. It dealt with 3043 applications for admission.

The *Tunbridge Wells office* dealt with 1241 applications for admission. It also deals with maternity bookings, and it is often used by doctors as an information bureau. The group chronic sick waiting-list is kept in the office. All cases received from general practitioners are referred to the group geriatrician, who visits the patients and informs the Tunbridge Wells office of his findings.

LONDON TEACHING HOSPITALS

BOARDS OF GOVERNORS

THE Minister of Health has made the following appointments, mainly to fill vacancies caused by the retirement of a third of the members, to the boards of governors of the 26 London teaching hospitals. Of 207 appointments, 169 are reappointments of retiring members. There are 5 appointments outstanding. The names of the medical profession are shown in bold type.

ROYAL HOSPITAL OF ST. BARTHOLOMEW

Reappointed : Sir Herbert Cohen, O.B.E. ; Sir **Henry Dale,** O.M., G.B.E., F.R.C.P., F.R.S. ; Prof. H. G. Jackson ; E. T. Neathercoat, C.B.E., J.P. ; A. McL. Niven, J.P. ; R. R. J. Turner, O.B.E. ; J. S. Weatherley.

New members : **E. R. Cullinan,** F.R.C.P. ; **O. S. Tubbs,** F.R.C.S.

LONDON HOSPITAL

Reappointed : Horace Denton ; Prof. B. Ifor Evans ; Miss Elizabeth Farrelly ; **D. W. C. Northfield,** F.R.C.S. ; V. C. Ponsonby, M.C. ; W. M. Pryor, D.S.O.

New members : Mrs. R. C. Littlejohn ; C. S. B. Wentworth-Stanley ; **Hermon Taylor,** F.R.C.S.

ROYAL FREE HOSPITAL

Reappointed : Alderman Mrs. Martin Smith, M.B.E. ; **Clifford Morson,** O.B.E., F.R.C.S. ; Prof. **Mary F. Lucas Keene,** M.B. ; Prof. T. S. Moore ; **J. D. McLaggan,** F.R.C.S. ; Prof. Winifred Cullis, C.B.E. ; W. E. Ford.

New member : A. H. Telling.

UNIVERSITY COLLEGE HOSPITAL

Reappointed : Prof. **S. J. Cowell,** F.R.C.P. ; D. R. Pye, C.B.E. ; **M. L. Formby,** F.R.C.S. ; A. Shefford, O.B.E. ; **E. A. Gregg,** L.R.C.P.I., J.P.

New members : Mrs. Margaret Harvey, J.P. ; Mrs. I. M. Bolton ; Sir Cosmo Parkinson, G.C.M.G., K.C.B., O.B.E.

MIDDLESEX HOSPITAL

Reappointed : Fred Messer, C.B.E., M.P., J.P. ; Simon Whitbread ; W. B. Morrison ; **M. H. Whiting,** O.B.E., F.R.C.S. ; Prof. **B. W. Windeyer,** F.F.R. ; Sir Eric Gore-Browne, D.S.O. ; L. F. Heald, K.C., M.P. ; C. G. Izard, O.B.E.

New member : Reginald Pestell, D.ECON., J.P.

CHARING CROSS HOSPITAL

Reappointed : H. E. Comben, A.M.I.C.E. ; Sir John Stewart-Wallace, C.B. ; **W. D. Southern,** M.R.C.S., L.D.S. ; David Trevor ; Mrs. Elsie O. Lindgren ; H. P. Marshall ; Hon. Mr. Justice Morris ; G. A. Pargiter, M.P.

New member : Mrs. Ann Blofield.

ST. GEORGE'S HOSPITAL

Reappointed : J. B. Bennie, J.P. ; Hon. Mrs. Reginald Coke ; E. O. Durlacher ; Mrs. Helga Feiling ; W. D. Little ; Sir Hugh Lucas-Tooth, M.P. ; **M. F. Nicholls,** F.R.C.S. ; **C. P. Pinckney,** F.R.C.P. ; R. H. Pott.

New members : Hon. **G. J. U. Bridgman,** F.R.C.S. ; I. F. Salmon (until March 31, 1951).

WESTMINSTER HOSPITAL

Reappointed : A. N. H. Baines ; Sir Frederick Bovenschen, K.C.B., K.B.E. ; **C. J. Gavey,** F.R.C.P. ; Mrs. R. Margeurite High ; **T. J. Millin,** F.R.C.S. ; **P. H. Mitchiner,** C.B., C.B.E., F.R.C.S. ; Sir Harry Vanderpant.

New members : Hon. Christopher Addison : H. Solomon ; Alderman Miss E. McCullough.

ST. MARY'S HOSPITAL

Reappointed : Sir **Alexander Fleming,** F.R.C.P., F.R.S., Miss **Esther Rickards,** F.R.C.S. ; Lord McGowan, K.B.E., Prof. **Wilfred D. Newcomb,** F.R.C.P. ; **Richard Doll,** M.D., F.R.C.P. ; I. M. Gluckstein ; A. H. Lee ; Lady Plummer ; H. L. Smedley.

New member : **W. D. W. Brooks,** F.R.C.P.

GUY'S HOSPITAL

Reappointed : S. B. Askew ; Alderman R. H. Burslem, J.P. ; E. V. Evans, O.B.E. ; Prof. **T. B. Johnston,** C.B.E., M.D. ; K. I. Julian ; Henry Levitt ; Prof. **W. R. Spurrell,** F.R.C.S. ; **F. S. Warner,** M.R.C.S., F.D.S.

New members : W. J. Driscoll ; Miss Mabel Crout.

KING'S COLLEGE HOSPITAL

Reappointed : Ralph Cocker ; **Terence East,** F.R.C.P., G. Hart ; H. L. Kendell ; Hon. Mrs. Charles Tufton, O.B.E.

New members : W. Trott ; **Sidney Thompson,** F.R.C.P. ; T. S. Stigger ; **Louis Minski,** F.R.C.P.

ST. THOMAS'S HOSPITAL

Reappointed : **G. H. Bateman,** F.R.C.S. ; **J. Bishop Harman,** F.R.C.P. ; R. J. Sainsbury ; Mrs. Doris A. Thomas ; **N. E. Waterfield,** F.R.C.S. ; S. W. Whiffen ; **J. M. Wyatt,** F.R.C.O.G. ; C. R. N. Winn, C.B., O.B.E., LL.M.

New members : Sir Herbert Thompson, C.I.E. ; Mrs. G. L. Rogers.

HAMMERSMITH, WEST LONDON AND ST. MARK'S HOSPITALS

Reappointed : E. G. Anthony, B.E.M. ; Prof. **Ian Aird,** F.R.C.S. ; Dame Katherine Jones ; **Horace Joules,** F.R.C.P. ; Prof. E. J. King, D.SC. ; **O. V. Lloyd-Davies,** F.R.C.S. ; Miss Amy Sayle, M.B.E. ; Mrs. M. Griffiths.

New member : J. B. Bennie, J.P.

HOSPITAL FOR SICK CHILDREN

Reappointed : **W. C. V. Brothwood,** M.D. ; Mrs. B. A. Beaumont, J.P. ; Miss E. V. Eckhard ; **G. H. Macnab,** F.R.C.S. ; Hon. Margaret Bigge ; Lady Thomas ; Theodore Magnus Wechsler, M.B.E. ; **I. A. B. Cathie,** M.D.

Parliament

School Dental Service

On the motion for the adjournment in the House of Commons on May 8, Squadron-Leader A. E. Cooper deplored that the school dental service should be one of the real casualties of the National Health Service. Dental officers were leaving the service to go into private practice, where they were able to earn four or five times the salaries they received from local authorities. The service was never adequate, but in 1948, 921 dentists were in the service. By January, 1950, the number had fallen to 738, and now it was lower still. The problem seemed to him to be twofold. First, there was the long-term problem of training sufficient dentists to cover both private requirements and the school dental service. Secondly, there was the immediate problem of maintaining the school dental service during the interim. Was it likely that the Whitley Council would award a scale of salaries which would give the school dental officers anything like the amount of money they could earn in private practice? If they did, the whole of our local government administration would be thrown out of balance, and the school dental officer would earn a higher salary than the town clerk. The only way in which this problem could be solved, he held, was for the Government to negotiate with the British Dental Association for a part-time service on a sessional basis with a somewhat higher fee than is paid today.

Mr. James Baird emphasised that the fixing of the school dentist's salary lay chiefly with the local authorities. There had been considerable improvements since 1945 and, under pressure from the Government, local authorities had gone a considerable way to meet school dental officers on the matter of salary. But authorities were often reluctant to give them the tools with which to do the job. Some school clinics were a disgrace and the equipment was in no way comparable with what a dentist would have in private practice. Also there was too much form filling. Every tiny authority had a senior dental officer who had to do so much book work each week. Why could not the Ministry of Health take the service over and organise it on a regional basis in collaboration with the Ministry of Education? He agreed that the only ultimate solution was more dentists. Till then he believed we might follow New Zealand's example and have dental hygienists—young girls who do two years' training under a dental surgeon and then are allowed to fill and extract children's teeth. He agreed that it was always doubtful to dilute a profession but if this dilution was limited to the treatment of school-children, under supervision all the time by qualified dental surgeons, he did not believe it would do much harm.

Dr. Charles Hill said the plain fact was that there were too few dentists today to provide a dental service for the community as a whole. Paradoxically the result of applying a dental service to the community as a whole had been most of all to deny it to the section of the community that needed it most. There was no doubt that among all the forms of dental care there was none to compare in terms of the health of the people with the dental care of school-children; yet at present a proportion of the children of the country were receiving no dental care whatever. Even though the position might be rectified in the next few months, it still remained true that those children had suffered dentally because of that lack of care. Some people might assert —Dr. Hill said he was not among them—that the terms in dental practice outside the school clinic had been over-attractive. Others would say, with much greater justice, that the remuneration of the school dental service had remained far too unattractive in relation to current conditions. The way to grapple with the situation was to give priority to the school population, whatever that might mean in the provision of dental care for the rest of the community, and secondly to produce new scales of remuneration for school dentists which would retain those still in the service and attract others to it. So urgent was the problem that intervention by the Minister was needed to secure the speediest possible adjustment of the situation.

Dr. Barnet Stross pointed out that dentists working in schools did not put in as many hours as a man working in private practice so that even if appropriate remuneration was given to the school dentists it would still not equal what could be earned outside it, and he believed young men of energy and vigour would still be attracted away from school medical service.

Mr. D. R. Hardman, parliamentary secretary to the Ministry of Education, replying to the debate, said he was anxious not to exacerbate the situation, because reports of one kind or another were awaited and negotiations were afoot for the setting up of Whitley machinery. He was convinced that the long-term solution of the problem was a great addition to the number of trained dentists. He hoped that as a result of recent developments Whitley machinery would be set up to deal with dentists in the employment of local authorities. The mission which had visited New Zealand to study the system of school dental nurses had returned to this country and their report was awaited with interest. If Whitley machinery were set up the question of salaries could at once be considered. No purpose could be served by concealing the fact that the school dental service was now in a very serious position.

Midwives Bill

In the House of Commons on May 8 Mr. Arthur Blenkinsop, parliamentary secretary to the Ministry of Health, moved the second reading of the Midwives (Amendment) Bill which has already passed through the House of Lords. He said it was a modest and non-controversial but useful measure. The Midwives Working Party had rejected the suggestion made in the report of the Working Party on Nurses that the Central Midwives Board might well combine with the General Nursing Council, and Mr. Blenkinsop agreed that it would be a mistake to mix the problem of ordinary health nursing with the work of the midwife. If a general body were set up there would be a danger that the midwives' side would be overweighted by the general nursing side.

The Working Party on Midwives had suggested that refresher courses should be made obligatory for all practising midwives, and the Royal College of Midwives had already increased the number of places for voluntary courses. It might be some time before provision was sufficient to allow the courses to be made compulsory. At the new college for midwives at Kingston full-time courses of six months' duration were beginning this month.

On the recommendation of the Working Party the Medical Research Council had set up a committee to find a more effective method of administration of analgesia by midwives, and it was hoped that their report would be received fairly shortly. The Ministry of Health were most anxious that other methods—for example 'Trilene'—might possibly be brought into more general use than at present, and by a recent amendment operating from April 1 this year, pethidine could now be procured and administered by midwives.

The clause in the Bill dealing with uniforms, he continued, had rather surprisingly caused discussion in the House of Lords where an amendment was carried which ensured that midwives should be entitled to wear the national uniform even if the local employing authority required the local uniform to be worn.

Mr. Somerville Hastings hoped that the Bill would be regarded by midwives as a gesture of appreciation by the nation for the work they had done. The death-rate of mothers in childbirth was a quarter of what it was 20 years ago; and the death-rate of infants had gone down, although not quite in the same proportion. For this they had to thank the midwives, at any rate in part. All doctors must also be grateful to the midwives, because, although not all of them would be ready to admit it, they all, he thought, without exception learned how to deal with a normal case of childbirth from a midwife. He feared that midwives were labouring today under a sense of grievance. They were not quite sure of their status and they were not too certain that they were able chemistry, mechanics, hydraulics, bacteriology, entomology, and parasitology. As the students will all be graduates, a sufficient knowledge of the physical sciences may be assumed, and attention will be devoted to their special applications to sanitation and to the biological sciences, which will be new material to most of the students. Secondly, there are the various fields of application such as water-supply, sewage disposal, housing and town planning, industrial hygiene, and pest control. Thirdly, there is the general background of public health against which the engineering studies may be seen in a right perspective. This involves instruction and practical experience in the organisation of the public-health services and in field epidemiology. This section, which will be carried out at the London School of Hygiene and Tropical Medicine, will bring the engineers into contact with medical men studying for the diploma in public health and with senior nurses, administrators, and other workers in the public services.

The Imperial College is well equipped for teaching the physical and biological sciences and the many engineering aspects of public health. The Royal College of Science possesses fully organised laboratories for teaching bacteriology, entomology, and parasitology, and these will be supplemented by field studies at its station at Silwood Park, near Ascot, which affords excellent opportunities for the practical application of various methods of mosquito control and for demonstrations of methods of rural sanitation, water-supply, and sewage disposal. In the City and Guilds College a laboratory is being set up for the physical and chemical analysis of water and sewage. Special apparatus will be used to determine the effects of different methods of treatment. Rooms will also be available for research. The laboratory work is to be supplemented by field tests on a pilot sewage-treatment plan at Oxford. In most cases the departments concerned are arranging courses specially adapted to the needs of civil engineers, and the Imperial College, which undertakes the greater part of the teaching, is offering all its library facilities to the students. With the generous assistance of the Rockefeller Foundation a special lecturer in public-health engineering has been appointed.

At the London School of Hygiene and Tropical Medicine the engineers will attend the same classes as the medical, nursing, and administrative postgraduate students. Indeed, as has already been mentioned, one of the main reasons for bringing the engineers to the school is to enable them to make contacts with other students in the same field. There are, however, certain subjects in which the engineers require special tuition as a group. For this purpose a medical lecturer has been appointed whose function it will be to supervise the training of the engineers and to see that their work is properly coördinated.

ADMISSION

The course is primarily intended for students holding a first degree in civil engineering, or an equivalent qualification, but students of equal status in other scientific subjects may also be accepted. Applications for admission to the course should be made as early as possible on the college entry form, which can be obtained from the Deputy Registrar, City and Guilds College, Exhibition Road, London, S.W.7. Students in India or Pakistan should send their applications through the office of the High Commissioner. Egyptian students should apply through the Egyptian Education Office.

Smallpox

Although several cases of suspected smallpox had been removed to hospitals in various parts of the country, on May 13 there was no known case of smallpox in England and Wales.

Estimates of Births

In his return for the week ended May 6, the Registrar-General gives the following estimates of live births to be expected in England and Wales during this and the next quarter: final estimate for the quarter ended June 30, 184,000; provisional estimate for the quarter ended Sept. 30, 176,000.

BEFORE THE WAR AND AFTER

REVIEW BY C.M.O.

On May 11 Sir Wilson Jameson, the retiring chief medical officer of the Ministry of Health, introduced to representatives of the press Sir John Charles, his successor; and he went on to survey the field of health today against the pre-war background.

Certain medical advantages had, he suggested, been won from the late war. The first of these was rapid progress in chemotherapy; and he cited mepacrine in particular. Before mepacrine was devised to replace the German atebrine, the annual malaria-rate among Australian Forces in New Guinea was 740 per 1000; with mepacrine the rate fell to 26 per 1000. The war had led, also, to improvement and extension of blood-transfusion. Last year donors had given 456,000 bottles of blood to the National Transfusion Service. This was a record, but hospitals were now using fifty times as much blood as before the war, and a further 200,000 donors were needed. The donors were at present mostly older people; and Sir Wilson hoped that younger volunteers would come forward. Among further medical benefits from the war were the Public Health Laboratory Service; the development of mass miniature radiography (Britain had the best 35 mm. mobile outfit in the world); extension of the welfare-foods and school milk and meals schemes (every day 9 out of 10 school-children were having milk at school, and half the children were having a meal there); publicity for health matters (notably in initiating and sustaining the diphtheria immunisation campaign and in bringing into the open the question of venereal disease); the development of reablement schemes; the initiation of special hospital centres for such specialties as neurosurgery, plastic surgery, thoracic surgery, and the treatment of the neuroses; and finally, arising from the war-time determination to build a new world, the National Health Service itself and the United Nations with its specialised agencies of which W.H.O. was one.

Turning to vital statistics, Sir Wilson compared figures for 1938 with figures (some provisional) for 1949 which had been supplied by the Registrar-General. The stillbirth-rate, which had been 38 per 1000 total births in 1938, was 23 per 1000 in 1949; and the infant-mortality rate had fallen from 53 per 1000 related live births in 1938 to 32 per 1000 in 1949. Maternal mortality—3·24 per 1000 total births in 1938—was 0·98 per 1000 in 1949.

In 1949 diphtheria deaths numbered 85 and notifications 1897, compared with 2861 deaths and 65,008 notifications in 1938. If the immunisation campaign was to be assured of success, 75% of children under 1 year of age must be inoculated; and in 1949 the percentage was within 5 of this goal. With regard to smallpox, only some 16% of infants were vaccinated in 1949—about half the proportion vaccinated before the repeal of the Vaccination Acts. From recent evidence it looked as if preventive inoculation at the height of a poliomyelitis epidemic might precipitate paralytic poliomyelitis; but there was no cause for undue concern, and the diphtheria immunisation campaign would continue.

Last year some 6300 cases of food-poisoning were notified. Sir Wilson attributed the increase in recent years partly to the more prevalent habit of eating in canteens; and he urged that those preparing food should have clean hands, and that cooked food which was not to be used until the next day should be rapidly cooled and placed in a refrigerator. As to pulmonary tuberculosis, he hoped that quite a number of cases would be treated in special wards of general hospitals.

elderly people requiring care and attention.—Mr. HECTOR McNEIL: I have no precise information on this subject but I certainly share my hon. Friend's anxiety that proper care and accommodation should be available for old people. Within the material and financial limits imposed by the present economic situation, hospitals and local authorities are doing all they can to meet this need. Mrs. MANN: Is the Minister aware that the medical profession are gravely perturbed at the number of old people who are merely senile and yet have to be certified as lunatics? Would he consider introducing some such certification as "aged and infirm"? Mr. McNEIL: While I think that rather odd things are happening, I have no precise information, and I have been offered none which would warrant the assumption made by my hon. Friend. However, on the second point, I certainly think there is a good case for considering some other description than that of certification, and I am looking closely at the point.

Mr. MALCOLM MACMILLAN: Would it be possible to put some form of pressure upon local authorities who only have permissive powers to do something more about institutional accommodation for old people who are not certifiable although they may be senile and in need of help?

Medicine and the Law

Fatal Error in Injection of Drugs

THE evidence at a recent Stockport inquest disclosed yet one more of the melancholy accidents due to the faulty working of what would seem to be a foolproof system of hospital practice. Two babies, each under three months old, were admitted to hospital for circumcision. Part of the preparation was the injection of gr. $^{1}/_{200}$ of atropine. By mistake morphine was injected instead of atropine. Efforts to revive the infants were carried on for hours but without success.

The medical evidence at the inquest indicated that both had died from morphine poisoning. A pathologist stated that he found a positive reaction for the morphine in the organs of one of the two bodies; tests on the other were negative, but it was possible for morphine to have caused death without leaving a trace.

How do these things happen, and how can they be prevented? The matron of the hospital explained that the dangerous drugs were kept in a locker cupboard in each ward. The practice was for drugs to be checked by a second nurse before administration; it was usual to check all drugs, including atropine, before any hypodermic injection. The ward sister said that she gave the key of the drug cupboard to a nurse to get gr. $^{1}/_{200}$ of atropine tablets and gr. $^{1}/_{2}$ of morphine. The drugs were in phials in tin boxes in the cupboard; each phial bore a tiny label. Apparently the part-time nurse took phials of atropine and morphine from the cupboard and placed them on a tray: she gave an adult patient an injection of morphine and replaced in the cupboard what she thought was the morphine phial; she dissolved in water what she thought were the tablets of atropine for the babies. A doctor told the coroner that the tubes were plainly and clearly labelled; if persons who were to give a dose could not read the label on the tube and could not appreciate what it meant, they should not be doing the job.

The coroner said the answer to the case was: "read the label on the phial." After retiring the jury announced that five of their number were in favour of a verdict of negligence not amounting to manslaughter and four in favour of negligence amounting to manslaughter. The coroner said that the smallest majority he could accept was one of seven to two. After a further retirement the proportion of five to four became one of seven to two. The verdict at an inquest matters less perhaps than the eliciting of the facts and the learning of the lesson.

In England Now

A Running Commentary by Peripatetic Correspondents

WHEN Professor Rhine spoke to the Royal Society of Medicine last week on extrasensory perception he took it for granted that his audience accepted the main tenets of statistical theory. I suppose that the psychologists present did so, but there was a solid mass of unbelievers around me at the back who shuddered every time the word statistics was used. Mind you, I'm not a statistician. or even a mathematician, so perhaps I've got it all wrong; but it seems to me that a statistician is rather like a bookie. The bookie does not say that Lightning *will* win and that Clodhopper *cannot*, he merely turns the general opinion on the likelihood of these events happening into figures, and then leaves it to us to take it or leave it. The bookies at Duke tell Professor Rhine that the odds are not 20–1 or 1000–1 but thousands of millions to one against his findings being due to chance. Out of the E.S.P. context this would be good enough for most of us. but there is such an intense emotional reaction against the whole of Rhine's hypothesis that the sceptics reject his figures. They cling desperately to more limited, nineteenth century, aspects of materialism and say "But they *could* be due to chance—they *must* be due to chance." Not very scientific.

After all, if a man forecast 25 matches in the penny-points every week. winter and summer, for eight years, and over that period got an average of 18 correct and more than once won the first prize with all correct. most people would conclude that he had some system and did not do it with a pin. But if I remember the figures rightly, one of Rhine's subjects made as many runs as this though she had to choose among five possibilities for each match and not three.

It's no good Professor Rhine coming to England and expecting us to believe in figures. We are not a logical nation. Let him put his best clairvoyant on to the football pools and see what happens. It may not be scientific, but if he wins a prize or two every week the whole of Britain will be convinced.

* * *

Let me tell you how we concluded a congress at Lyons this May.

On the Sunday morning, when a blue sky and church bells had early filled the streets with people, we stopped at a "pharmacie" in Villefranche-sur-Saône, and "M. l'organiseur" of the excursion rang the bell to summon his colleague. The willing doctor removed his white coat, and, deserting for a while his "laboratoire d'analyse," led the convoy of automobiles to the village of Saint Julien, whence we proceeded on foot through white dusty lanes to a simple cottage draped with blossoms of lilac and wistaria. Here was born, on July 12. 1813, Claude Bernard, the son of a peasant. In the unchanged courtyard surrounded by hawthorns and robinias three small children played in the shade of an elegant horse-chestnut tree. On a bench nearby lay their "poupées" with faces upturned to the blazing sun. Within the house, now converted into a museum, we studied his early prose drama, "Arthur de Bretagne" and the equipment which the great physiologist used to such good purpose in the Laboratoire de Saint Julien, including the Judas tree twig which spanned a small staining trough. On a wall hung a certificate of membership of the Medico-Chirurgical Society of Edinburgh, signed by Robert Omond, D. Argyll Robertson. and T. Grainger Stewart and dated April 7, 1867. A door in the wall of the garden, which surmounted a hillock, revealed in panorama the gold-capped hills of Beaujolais, sandy valleys, tidy vineyards, and prosperous villas with red roof tiles.

After a visit to the "chapitre de Salles," an old-world monastery of considerable charm, we hurried on to an auberge chosen with care by the "syndicat d'initiatif" of the congress and "exploité par la société pour l'expansion vinicole et gastronomique." We were late on arrival and were already salivating for "les andouillettes beaujolaises au vin blanc" which had been long scheduled in advance to open the "repas." We were 65 in number.

to do as good work as they once did. Mr. Hastings said he did not want to suggest that it was only the midwives who feared this loss of status. Dr. Collings, the Australian doctor, who had recently published a report on general practice in England, had said: "All the midwives, local-authority doctors, and consultant obstetricians with whom I have spoken expressed the hope that the G.P.s who are now booking midwifery cases will leave the actual work to the midwives and clinics." Mr. Hastings said that that statement suggested that the apprehension as to status of the midwives, and the capacity for doing their best for their patients, which he knew some of them felt, was not entirely groundless. He was glad that this little Bill would at any rate help them in some ways to raise their status. He regretted, however, that there was nothing in the measure to permit a midwife to call in, when necessary, a doctor who she could be assured knew more about midwifery than she did herself, and who could be of real help to her.

Dr. CHARLES HILL believed that the present system, under which a woman selected her doctor in advance—the doctor of her choice, that doctor in most cases being on the approved list for the purpose and remaining liable to be called in on the confinement, or being free to attend the confinement if he thought fit—was a substantial improvement over the old system under which, all too often, doctors called in on an emergency saw the patient for the first time. He would remind Mr. Hastings that to a substantial extent the present system arose in the minds of the women themselves. They believed that in a satisfactory maternity service the individual citizen should have, as one of the benefits of the service, the right to be attended by her own doctor through the antenatal period, and, if necessary, in the confinement.

Mr. ANEURIN BEVAN reminded Dr. Hill that it was always regarded as one of the conditions for this new arrangement that there should be a general-practitioner obstetrical panel sufficiently small to enable enough experience to be obtained in confinement by the general practitioner, and that the object of a scheme might be defeated if too many general practitioners put their names on the panel.

Dr. HILL replied that it did not necessarily prove excellence in all areas for the numbers to be small; but he agreed with the Minister's general proviso that those whose names appeared on the approved list should be able to enjoy sufficient continuing practice to maintain their skill in obstetrics. Subject to that proviso, it was clearly desirable in the public interest, and in accordance with the wishes of the women, that they should have the services of midwife and approved doctor working in collaboration.

The Bill was read a second time and the necessary financial resolution was agreed to in Committee.

Reduction of Dental Fees

On May 15 Mr. J. BAIRD moved to annul the N.H.S. regulation of April 24 which imposes a further cut of 10% on the fees earned by dentists. He did so, he said, not because he objected to a cut, but because he objected to the way in which it was done. The new cut applied to all sections of the dental profession, and the good and bad would suffer alike. In his reply Mr. ARTHUR BLENKINSOP explained that the Ministry were anxious to have alternative proposals as to the way in which the reductions could be made, but they felt the reductions were a matter of urgency which could not be left for an indefinite time while alternative proposals were worked out. They were not putting forward this scheme as a final proposal, and in a letter to the British Dental Association the Minister had agreed to consider the substitution of a sliding scale applicable to higher earnings. Mr. Blenkinsop appealed to the dental profession to resume negotiations. The sooner they did so, the sooner could an alternative scheme be introduced.

QUESTION TIME

Practice Expenses

Dr. CHARLES HILL asked the Minister of Health what period would be covered by his proposed investigation into the ratio of practice expenses to gross remuneration in the case of general practitioners in the National Health Service.—Mr. BEVAN replied: I propose to discuss with the profession the scope of the investigation but it is unlikely that figures for any period later than the year ended Dec. 31, 1949, will be available. Dr. HILL: In view of the fact that since the end of that period motoring costs have risen as a result of the petrol duty and emoluments have been correspondingly reduced, does not the Minister agree that the result of such an inquiry would be correspondingly less accurate and less valuable? Mr. BEVAN: I do not propose to prejudge the nature of the investigation. I am quite sure that the representatives of the medical profession will call the attention of the negotiating authorities to that point. Mr. ELLIS SMITH: We can depend on that.

Mr. E. B. WAKEFIELD: Is the Minister aware that the expenses of country practitioners are likely to rise by anything from £40 to £60 a year as a result of the increase in the price of petrol? Mr. BEVAN: If I may say so with all respect, I think that it is undesirable that the position of one profession in the whole of the National Health Service should be the subject of pressure groups in the House of Commons.

Employment of Medical Assistants

Mr. HASTINGS asked the Minister if he was satisfied that reasonable facilities existed to enable those doctors who had increased their experience by acting as assistants to general practitioners under the National Health Service Act to secure direct employment under the Act.—Mr. BEVAN replied: I am not sure what my hon. friend has in mind, but I think these doctors have reasonable opportunities for getting into general practice as principals under the health service.

Mr. HASTINGS: What proportion of the general practitioners who have accepted service under the National Health Service Act have assistants working with them; and how many of such assistants have become partners since July 5, 1948? Mr. BEVAN: The percentage at Jan. 1, 1950, was about 10%; so far as is known rather more than 300 assistants have become partners of their previous principals since July 5, 1948.

Mr. HASTINGS: Does the Minister realise the extreme difficulties that young men have in starting in general practice today, and will he institute an inquiry to see whether something more can be done? Mr. BEVAN: My hon. friend is not quite correct in that statement. There are areas in the country which the Medical Practices Committee have declared available. Doctors can go there and, to use a colloquialism, can squat; but they do not want to go to the undesirable areas; they want to go to particular areas.

Dental Fees

Lieut.-Colonel D. L. LIPTON: Does machinery exist for dealing with dentists who have turned away patients solely on the pretext that their fees have now been cut? Mr. BEVAN: I have no recent information about dentists doing that, but the Ministry of Health is continually contending with the low standards of some of the dentists.

Mr. SOMERVILLE HASTINGS asked if the Minister agreed that it was practically impossible to ensure good quality work when dentists were paid for the work done.—Mr. BEVAN: It is, of course, always impossible to guarantee a certain standard of professional skill and attention. That can only be done by raising the standards of the dental profession.

Sealed Bed-pan Washers

Wing-Commander G. P. STEVENS asked the Minister if he was aware of the unpleasantness and danger to hospital staffs of the open type of bed-pan sluice; and if he would take steps to hasten the installation of the seal type of bed-pan washer as a matter of urgency.—Mr. BEVAN replied: I am advised that this change is gradually taking place, but that any general conversion would not justify the cost involved.

Accommodation for Aged in Scotland

Mrs. JEAN MANN asked the Secretary of State for Scotland whether he was aware that certification of old people was increasing in Scotland because a bed in an institution was required; and if he would remove this stigma from the elderly people requiring care and attention.—Mr. HECTOR McNEIL: I have no precise information on this subject but I certainly share my hon. Friend's anxiety that proper care and accommodation should be available for old people. Within the material and financial limits imposed by the present economic situation, hospitals and local authorities are doing all they can to meet this need. Mrs. MANN: Is the Minister aware that the medical profession are gravely perturbed at the number of old people who are merely senile and yet have to be certified as lunatics? Would he consider introducing some such certification as "aged and infirm"? Mr. McNEIL: While I think that rather odd things are happening, I have no precise information, and I have been offered none which would warrant the assumption made by my hon. Friend. However, on the second point, I certainly think there is a good case for considering some other description than that of certification, and I am looking closely at the point.

Mr. MALCOLM MACMILLAN: Would it be possible to put some form of pressure upon local authorities who only have permissive powers to do something more about institutional accommodation for old people who are not certifiable although they may be senile and in need of help?

Medicine and the Law

Fatal Error in Injection of Drugs

THE evidence at a recent Stockport inquest disclosed yet one more of the melancholy accidents due to the faulty working of what would seem to be a foolproof system of hospital practice. Two babies, each under three months old, were admitted to hospital for circumcision. Part of the preparation was the injection of gr. $^1/_{200}$ of atropine. By mistake morphine was injected instead of atropine. Efforts to revive the infants were carried on for hours but without success.

The medical evidence at the inquest indicated that both had died from morphine poisoning. A pathologist stated that he found a positive reaction for the morphine in the organs of one of the two bodies; tests on the other were negative, but it was possible for morphine to have caused death without leaving a trace.

How do these things happen, and how can they be prevented? The matron of the hospital explained that the dangerous drugs were kept in a locker cupboard in each ward. The practice was for drugs to be checked by a second nurse before administration; it was usual to check all drugs, including atropine, before any hypodermic injection. The ward sister said that she gave the key of the drug cupboard to a nurse to get gr. $^1/_{200}$ of atropine tablets and gr. $^1/_2$ of morphine. The drugs were in phials in tin boxes in the cupboard; each phial bore a tiny label. Apparently the part-time nurse took phials of atropine and morphine from the cupboard and placed them on a tray: she gave an adult patient an injection of morphine and replaced in the cupboard what she thought was the morphine phial; she dissolved in water what she thought were the tablets of atropine for the babies. A doctor told the coroner that the tubes were plainly and clearly labelled; if persons who were to give a dose could not read the label on the tube and could not appreciate what it meant, they should not be doing the job.

The coroner said the answer to the case was: "read the label on the phial." After retiring the jury announced that five of their number were in favour of a verdict of negligence not amounting to manslaughter and four in favour of negligence amounting to manslaughter. The coroner said that the smallest majority he could accept was one of seven to two. After a further retirement the proportion of five to four became one of seven to two. The verdict at an inquest matters less perhaps than the eliciting of the facts and the learning of the lesson.

In England Now

A Running Commentary by Peripatetic Correspondents

WHEN Professor Rhine spoke to the Royal Society of Medicine last week on extrasensory perception he took it for granted that his audience accepted the main tenets of statistical theory. I suppose that the psychologists present did so, but there was a solid mass of unbelievers around me at the back who shuddered every time the word statistics was used. Mind you, I'm not a statistician, or even a mathematician, so perhaps I've got it all wrong; but it seems to me that a statistician is rather like a bookie. The bookie does not say that Lightning *will* win and that Clodhopper *cannot*, he merely turns the general opinion on the likelihood of these events happening into figures, and then leaves it to us to take it or leave it. The bookies at Duke tell Professor Rhine that the odds are not 20–1 or 1000–1 but thousands of millions to one against his findings being due to chance. Out of the E.S.P. context this would be good enough for most of us, but there is such an intense emotional reaction against the whole of Rhine's hypothesis that the sceptics reject his figures. They cling desperately to more limited, nineteenth century, aspects of materialism and say "But they *could* be due to chance—they *must* be due to chance." Not very scientific.

After all, if a man forecast 25 matches in the penny-points every week, winter and summer, for eight years, and over that period got an average of 18 correct and more than once won the first prize with all correct, most people would conclude that he had some system and did not do it with a pin. But if I remember the figures rightly, one of Rhine's subjects made as many runs as this though she had to choose among five possibilities for each match and not three.

It's no good Professor Rhine coming to England and expecting us to believe in figures. We are not a logical nation. Let him put his best clairvoyant on to the football pools and see what happens. It may not be scientific, but if he wins a prize or two every week the whole of Britain will be convinced.

* * *

Let me tell you how we concluded a congress at Lyons this May.

On the Sunday morning, when a blue sky and church bells had early filled the streets with people, we stopped at a "pharmacie" in Villefranche-sur-Saône, and "M. l'organiseur" of the excursion rang the bell to summon his colleague. The willing doctor removed his white coat, and, deserting for a while his "laboratoire d'analyse," led the convoy of automobiles to the village of Saint Julien, whence we proceeded on foot through white dusty lanes to a simple cottage draped with blossoms of lilac and wistaria. Here was born, on July 12, 1813, Claude Bernard, the son of a peasant. In the unchanged courtyard surrounded by hawthorns and robinias three small children played in the shade of an elegant horse-chestnut tree. On a bench nearby lay their "poupées" with faces upturned to the blazing sun. Within the house, now converted into a museum, we studied his early prose drama, "Arthur de Bretagne" and the equipment which the great physiologist used to such good purpose in the Laboratoire de Saint Julier, including the Judas tree twig which spanned a small staining trough. On a wall hung a certificate of membership of the Medico-Chirurgical Society of Edinburgh, signed by Robert Omond, D. Argyll Robertson, and T. Grainger Stewart and dated April 7, 1867. A door in the wall of the garden, which surmounted a hillock, revealed in panorama the gold-capped hills of Beaujolais, sandy valleys, tidy vineyards, and prosperous villas with red roof tiles.

After a visit to the "chapitre de Salles," an old-world monastery of considerable charm, we hurried on to an auberge chosen with care by the "syndicat d'initiatif" of the congress and "exploité par la société *pour l'expansion vinicole et gastronomique*." We were late on arrival and were already salivating for "les andouillettes beaujolaises au vin blanc" which had been long scheduled in advance to open the "repas." We were 65 in number.

to do as good work as they once did. Mr. Hastings said he did not want to suggest that it was only the midwives who feared this loss of status. Dr. Collings, the Australian doctor, who had recently published a report on general practice in England, had said: "All the midwives, local-authority doctors, and consultant obstetricians with whom I have spoken expressed the hope that the G.P.s who are now booking midwifery cases will leave the actual work to the midwives and clinics." Mr. Hastings said that that statement suggested that the apprehension as to status of the midwives, and the capacity for doing their best for their patients, which he knew some of them felt, was not entirely groundless. He was glad that this little Bill would at any rate help them in some ways to raise their status. He regretted, however, that there was nothing in the measure to permit a midwife to call in, when necessary, a doctor who she could be assured knew more about midwifery than she did herself, and who could be of real help to her.

Dr. CHARLES HILL believed that the present system, under which a woman selected her doctor in advance—the doctor of her choice, that doctor in most cases being on the approved list for the purpose and remaining liable to be called in on the confinement, or being free to attend the confinement if he thought fit—was a substantial improvement over the old system under which, all too often, doctors called in on an emergency saw the patient for the first time. He would remind Mr. Hastings that to a substantial extent the present system arose in the minds of the women themselves. They believed that in a satisfactory maternity service the individual citizen should have, as one of the benefits of the service, the right to be attended by her own doctor through the antenatal period, and, if necessary, in the confinement.

Mr. ANEURIN BEVAN reminded Dr. Hill that it was always regarded as one of the conditions for this new arrangement that there should be a general-practitioner obstetrical panel sufficiently small to enable enough experience to be obtained in confinement by the general practitioner, and that the object of a scheme might be defeated if too many general practitioners put their names on the panel.

Dr. HILL replied that it did not necessarily prove excellence in all areas for the numbers to be small; but he agreed with the Minister's general proviso that those whose names appeared on the approved list should be able to enjoy sufficient continuing practice to maintain their skill in obstetrics. Subject to that proviso, it was clearly desirable in the public interest, and in accordance with the wishes of the women, that they should have the services of midwife and approved doctor working in collaboration.

The Bill was read a second time and the necessary financial resolution was agreed to in Committee.

Reduction of Dental Fees

On May 15 Mr. J. BAIRD moved to annul the N.H.S. regulation of April 24 which imposes a further cut of 10% on the fees earned by dentists. He did so, he said, not because he objected to a cut, but because he objected to the way in which it was done. The new cut applied to all sections of the dental profession, and the good and bad would suffer alike. In his reply Mr. ARTHUR BLENKINSOP explained that the Ministry were anxious to have alternative proposals as to the way in which the reductions could be made, but they felt the reductions were a matter of urgency which could not be left for an indefinite time while alternative proposals were worked out. They were not putting forward this scheme as a final proposal, and in a letter to the British Dental Association the Minister had agreed to consider the substitution of a sliding scale applicable to higher earnings. Mr. Blenkinsop appealed to the dental profession to resume negotiations. The sooner they did so, the sooner could an alternative scheme be introduced.

QUESTION TIME

Practice Expenses

Dr. CHARLES HILL asked the Minister of Health what period would be covered by his proposed investigation into the ratio of practice expenses to gross remuneration in the case of general practitioners in the National Health Service.—Mr. BEVAN replied: I propose to discuss with the profession the scope of the investigation but it is unlikely that figures for any period later than the year ended Dec. 31, 1949, will be available. Dr. HILL: In view of the fact that since the end of that period motoring costs have risen as a result of the petrol duty and emoluments have been correspondingly reduced, does not the Minister agree that the result of such an inquiry would be correspondingly less accurate and less valuable? Mr. BEVAN: I do not propose to prejudge the nature of the investigation. I am quite sure that the representatives of the medical profession will call the attention of the negotiating authorities to that point. Mr. ELLIS SMITH: We can depend on that.

Mr. E. B. WAKEFIELD: Is the Minister aware that the expenses of country practitioners are likely to rise by anything from £40 to £60 a year as a result of the increase in the price of petrol? Mr. BEVAN: If I may say so with all respect, I think that it is undesirable that the position of one profession in the whole of the National Health Service should be the subject of pressure groups in the House of Commons.

Employment of Medical Assistants

Mr. HASTINGS asked the Minister if he was satisfied that reasonable facilities existed to enable those doctors who had increased their experience by acting as assistants to general practitioners under the National Health Service Act to secure direct employment under the Act.—Mr. BEVAN replied: I am not sure what my hon. friend has in mind, but I think these doctors have reasonable opportunities for getting into general practice as principals under the health service.

Mr. HASTINGS: What proportion of the general practitioners who have accepted service under the National Health Service Act have assistants working with them; and how many of such assistants have become partners since July 5, 1948? Mr. BEVAN: The percentage at Jan. 1, 1950, was about 10%; so far as is known rather more than 300 assistants have become partners of their previous principals since July 5, 1948.

Mr. HASTINGS: Does the Minister realise the extreme difficulties that young men have in starting in general practice today, and will he institute an inquiry to see whether something more can be done? Mr. BEVAN: My hon. friend is not quite correct in that statement. There are areas in the country which the Medical Practices Committee have declared available. Doctors can go there and, to use a colloquialism, can squat; but they do not want to go to the undesirable areas; they want to go to particular areas.

Dental Fees

Lieut.-Colonel D. L. LIPTON: Does machinery exist for dealing with dentists who have turned away patients solely on the pretext that their fees have now been cut? Mr. BEVAN: I have no recent information about dentists doing that, but the Ministry of Health is continually contending with the low standards of some of the dentists.

Mr. SOMERVILLE HASTINGS asked if the Minister agreed that it was practically impossible to ensure good quality work when dentists were paid for the work done.—Mr. BEVAN: It is, of course, always impossible to guarantee a certain standard of professional skill and attention. That can only be done by raising the standards of the dental profession.

Sealed Bed-pan Washers

Wing-Commander G. P. STEVENS asked the Minister if he was aware of the unpleasantness and danger to hospital staffs of the open type of bed-pan sluice; and if he would take steps to hasten the installation of the seal type of bed-pan washer as a matter of urgency.—Mr. BEVAN replied: I am advised that this change is gradually taking place, but that any general conversion would not justify the cost involved.

Accommodation for Aged in Scotland

Mrs. JEAN MANN asked the Secretary of State for Scotland whether he was aware that certification of old people was increasing in Scotland because a bed in an institution was required; and if he would remove this stigma from the

Letters to the Editor

THE REGISTRAR'S FUTURE

SIR,—The Colonial Service is not as obvious a solution of the problem of the senior registrar in the thirties as Mr. Mitchiner suggests in his letter of May 6.

Firstly, there is a great deal to be learned about the country, the people, and the diseases of any tropical colony before a man becomes a useful medical officer or is fit to be any kind of specialist therein, as the R.A.M.C. found to its cost during the wars. At least two or three years of general duties is necessary for this. Secondly, the retiring age is relatively early, and he will have to start life again in the late forties or early fifties, with only a very small pension and no hope at all of finding a post in the U.K. where he can practise his specialty.

Even if he decides that he might tolerate general practice, this has in effect been closed to him by the advent of the N.H.S. The B.M.A. has admitted that its bureau has great difficulty in placing men over 40. Some time ago, as a matter of interest, I wrote to an executive council that advertised a vacancy, asking if it was likely that an application from a retired colonial medical officer would be considered. The reply was No; it was experience in general practice that was taken into account when recommending appointments.

Certainly the actual work in most branches of the Colonial Service is as interesting and colourful as anything could be, though a great strain; that it has failed to attract is directly due to Colonial Office mismanagement. But I should advise anyone who does join to get in as young as he can, and not more than three years after qualification.

Bristol. G. L. ALEXANDER.

SIR,—Mr. Mitchiner's letter of May 6 makes depressing reading, but not entirely in the sense that he intended. It is distressing to find one who has risen to the top of the tree in his profession, presumably not without struggle, counselling caution and the easier path to his juniors. Of course the prospect for professional advancement in this country in the immediate future is not rosy—no-one knows that better than we registrars ourselves. I doubt, however, if it has ever been particularly certain. In the natural sequence of events some of us will attain our ambitions in a specialty and the majority will turn to some other sphere, but that is no reason for raising the bogy of "competition" in an attempt to discourage at this late stage those who decided years ago on the course they would pursue. The creation of a vast number of registrar posts—some feel in order to obtain cheap quasi-consultant labour—has only aggravated the perennial state of competition, not created a new problem. There are still those who hold that competition brings out the best: surely what we need in this country now.

What are Mr. Mitchiner's alternatives? The Services? Six and a half years' service during the late war showed me enough of Service medicine from the inside to convince me that nothing short of another war would ever persuade me to expose myself to such a stultifying experience again. The "serious shortage of specialists of many sorts in the medical services of the Fighting Forces," which Mr. Mitchiner holds out as an inducement to join, is merely an indication that many others share this opinion. The Colonial Medical Service? A few minutes' conversation with one of its members, and a perusal of correspondence on the subject in the medical press during the last year or so, will be enough to dissuade anyone whose ambition it is to practise his profession to the best of his ability. Overseas university and university college posts? Delightful, but how many are there? The numbers advertised during the last year amount to a handful. In addition there are the problems—also present in the two foregoing examples—of separation from one's family and adequate schooling for one's children abroad.

No—the race is not always to the swift, nor the battle to the strong, and I hope that such of my fellow registrars (and competitors) who believe they have it in them to succeed will stick it out and disregard both well-meant advice and subtle attempts to evade the results of faulty planning in the past. Presumably all hope for our profession in this country has not come to a full stop in 1950.

Beaconsfield, Bucks. M. C. T. REILLY.

CHRONIC SKIN ULCERATION

SIR,—I am sure that Mr. Troensegaard-Hansen will forgive me if I criticise the form of treatment he describes in your issue of May 6.

First of all, he states that amniotic membrane possesses some specific healing power and that it is used to close dural defects. It is indeed used for this purpose, but not because of its healing power, but purely (so I gather from neurosurgeons) to prevent adhesions of the brain to the overlying bone. Then he goes on to say: "This stimulation of fibrous-tissue growth, combined with my own observations on epithelial repair, convinced me that amnion was an ideal covering for chronic skin ulcers." Surely there is far too much fibrous tissue in and around leg ulcers which already prevents epithelisation and healing. The amniotic membrane is boiled for seven minutes before use. Surely the boiling will kill any epithelising properties that the amniotic graft may have had?

I notice that Mr. Troensegaard-Hansen says the patient is admitted to hospital, and the ulcer is scraped with a Volkmann's spoon under a general anæsthetic. We all know that many of these ulcer cases can be cured by putting the patient (and the ulcer) to bed. But how many of these patients can we admit to hospital these days when beds are scarce? And again, how many of the patients who are working housewives are willing, or even able, to take time off to come into hospital or even to rest at home for ten weeks, as Mr. Troensegaard-Hansen advises?

Most surgeons agree that in many of these cases, even when a skin graft is applied to the ulcer, ulceration quite often recurs; and this is not surprising since the underlying causes of the ulceration are still present. It follows, therefore, that these cases must be re-examined regularly.

For many years I have treated the more intractable cases by what I call the "darn" graft. This treatment, which requires no hospitalisation, consists in darning whole-thickness skin in and out through the granulations of the ulcer.

The ulcer area is sterilised one week before by the application of streptomycin compresses.

The strips of skin for grafting are taken from the patient's thigh, which has been infiltrated with procaine and adrenaline. The strips of skin, which are roughly 5 mm. wide, are cut to the length required with a sharp scalpel; as many grafts as are required are cut. These grafts are raised from the underlying fat by means of short sharp-pointed scissors, such as are used in plastic surgery. After the grafts are cut, the defect in the thigh is made good by stitching the skin edges together. Each piece of skin is now tied at one end to a piece of fine thread, the other end of which is threaded through a small curved needle.

The grafts are now darned in and out through the ulcer bed from one side of the ulcer to the other. In this way the area becomes covered with skin-strips, some part of the strips lying on the granulation surface and some being buried beneath the surface. The area is dusted over lightly with penicillin powder: tulle gras, or, as I prefer, 'Uro-sulphonet' (Dalmas), is applied, then gauze, and finally elastic adhesive bandage.

In the tiny kitchen which adjoined the dining-room a plump and overheated chef was tumbling dismembered cockerels into a huge casserole of wine. Vats of aromatic bouillon simmered nearby. At the solitary table littered with a mélange of vegetables, cheeses, cutlets of meat, fruit, flagons of wine and oil, and bowls of fresh creamy butter, besides a wealth of garnitures, two assistants were seated leisurely enjoying "saucisson en croûte"; another was slicing mushrooms. Outside in the garden and in the glare of the sun we searched for that which was not to be found, and climbing the short outside staircase washed in turn at a small wall fountain. Cheerful and neatly dressed maids hurried past us with bowls of "salade mimosa" for a party of tourists relegated to the barn. As we filed once more through the kitchen the grinning chef was decanting "double-crême" into a cauldron of tiny young peas, while Madame was filling carafes and even teapots with water for her dehydrated guests.

Communications at the congress may have been limited to three minutes each, but these worthy folk do not hurry over their meals. There is some advantage in this, for it does allow one to keep up to date. We began our apéritif at 13.53, reached the "filet de bœuf Pêrigueux aux sarments" (first helping, and the signal for the opening of the "Domaine de la grand-cour") at 15.18 and the "chabichon" at 16.25. Then during one of many intervals in which the most good-natured of overworked women washed stacks of dishes, we listened to speeches, drank to the ladies of France, and sang the Belgian, British, and French national anthems. The "bombe maison," which melted quickly in the heat of the crowded room, arrived at 17.12, while "les corbeilles de fruit" and café were finally dispatched at 17.44.

On the way back, faithful to our calling, we visited the Musée Ramet at Moulin à Vent, and displayed lively interest in the parasitology of grapes. It was with some relief that we learnt on sampling the wine, served appropriately on upturned barrels in the courtyard at the personal invitation of "le propriétaire du crû," that disease had been effectively eradicated.

To make doubly sure, we called at the Château Pizay, by which time it was already twilight. As we drove up the avenue of lopped "platanes" we admired the noble proportions of the castle with its steep blue-grey tiled roof and the stately chapel of marble which flanked the forecourt. Here, behind a massive iron gateway, sat a fearsome Alsatian proudly teaching her pup to guard the entrance to "les caves." Lights shone from a few of the principal rooms, but one by one the shutters were being drawn. In the walled garden a nightingale sang as we admired the skill of the topiarist and the beauty of a tamarisk tree. In this delightful setting we were to learn the importance of temperature control and of skilled handling for the maturation of wine. Still thirsting for scientific knowledge, we tested the red Morgon, the white, and also the château-bottled.

Your reporter's last impression of this memorable and varied congress is of devoted colleagues standing under a solitary cobwebbed light in the coolth of an endless vault with its vista of casks arranged on the sandy floor. With glasses at the ready, their eyes were fixed on a vintner who, with the aid of a ladder, was silhouetted surmounting a particularly large barrel. In his hand he held an ingenious pipette with which he removed, at the instigation of "M. le régisseur du château," generous samples for the favour of our opinion. Seldom had our scientific training stood us in such good stead.

* * *

I had never attended the Nurses' Prizegiving and I accepted Matron's kind invitation rather doubtfully. However, the whole affair proved most enjoyable. Stiffness and starchiness were only apparent in the nurses' uniforms, and my word!—what stiffness and what starchiness! I thought my shirt was white (*pace* Messrs. Persil) but it looked grey against that dazzling sea of starch.

The proceedings were held in the pathology museum, and most of the specimens were tactfully hidden from view, though one elderly woman hardly suppressed a scream when she saw a hairy teratoma gnashing its single tooth at her. A paraphrase, well sung by the nurses but not quite so well by the audience, set the ball rolling. We were not provided with the words, and I suspect that at least one member of the platform party sang the agenda. Nevertheless, most of us put up a fair show and were not led astray by our hearty E.N.T. colleague booming out verse 4 during verse 3 and then proclaiming a loud amen with one verse still to come....

The Chairman briefly introduced the lady who was to present the awards, and soon a miscellany of bright nurses were receiving medals, books, and certificates. It was a pleasure to see a really bonny lass receive the gold medal. At school one so often saw grim creatures with bloodshot eyes and pale bulbous foreheads creep on to the platform to receive their prize, before tottering off to a sanatorium or being led gently away to a psychiatrist. When the gracious lady had presented the last uplifting tome she was given a beautiful bouquet, and after sundry votes of thanks the meeting closed with a photograph of Matron sitting proudly amid the successful nurses and the platform party. The company then adjourned for tea, which was enjoyed by all, except perhaps the woman who had seen the teratoma.

It's only a matter of weeks now before George, my psychologist friend, completes his paper on *Personality Traits as Revealed by Urine;* but what a long one it could have been if he'd spent a few more months as a G.P.! First there's the kind of bottle in which the specimen arrives—orange-juice containers from the antenatals, milk bottles from the housewife, and beer bottles from her husband, but with innumerable and no doubt revealing minor variations. My housekeeper has now accustomed herself to finding two or three pint bottles of urine on the doorstep in the morning and she no longer accuses the milkman of foul play. Then there are the additions, mostly accidental but some purposive; one purist added a few drops of 'Dettol,' "So that it wouldn't go bad, Doctor." And lastly the labels: my bank manager's, for instance, is marked "Private and Confidential"; and in that busy Christmas week how comforting it was to receive a specimen gaily decorated in festive paper and stamped "Do not open before December 25th."

A problem arose when my kindly publican patient slipped a paper-wrapped bottle into my hand on parting; my well-trained fingers immediately diagnosed it as a whisky bottle; but should I assume the best and thank him warmly, or the worst and say I'd let him know the result later? The only major disaster that has been caused by this sort of confusion in my experience was when I tested and marked n.a.d. the last few drops of my senior partner's priceless "Old Smuggler 1900" he had carelessly left on the hall table. He is now actively lobbying the Minister to supply special bottles for urine collection.

Hardly had poor Mr. Rank sunk back into his fauteuil with a sigh of relief after being found Not Guilty of causing juvenile crime (minority dissenting) than *Picture Post* bashed him for causing childhood neurosis. Still reeling under this he will have to face my forthcoming thesis. Our rapidly peripatetic coroner's pathologist (was the phrase "the quick and the dead" first used in this context?) tells me that he has had a lot of suicides by precipitation recently and asks the cause. That's obvious. It's all because of the Pictures. Without thought or research I quoted *The Red Shoes*, *The Astonished Heart*, and *Mine Own Executioner*, all of which suggest this way of ending one's troubles. If only the revival of *Mayerling* had lasted longer we would have had a change in suicidal fashion. When I elaborate this preliminary communication *The Lancet* shall have my article.

* * *

One of our patients on 'Antabus' treatment had a persistently uneventful reaction with the weekly test dose of brandy. With characteristic ingenuity he suggested that he should have the brandy every day and the tablets only on test days.

iberculosis, early diagnosis of meningitis is essential, nd that can only be achieved by routine weekly examination of the cerebrospinal fluid for the characteristic hanges, including the appearance of tubercle bacilli.

VITAMIN B_{12} DIURESIS

SIR,—In their letter last year[1] Dr. Barnard and Dr. Veitzner stated that single injections of 45–75 µg. of itamin B_{12} produced definite diuresis in 12 out of 16 ubjects. This was attributed to the cobalt contained n the vitamin.

We have failed to detect any diuresis after single njections of 40–60 µg. given to 4 patients. The first 2 patients were suffering from cirrhosis of the liver with noderate ascites; there was no evidence of renal disease ind they used to respond well to 'Mercuphylline' njections. The 3rd patient was also suffering from cirrhosis with ascites and macrocytic anæmia: the Wassermann reaction was positive, ++. He used to respond well to mercuphylline injections. The 4th was a boy, aged 14 years, who had chronic malaria and anæmia which responded to iron and antimalarial therapy. He had no evidence of renal disease. The results were as follows:

	Case 1	*Case 2*	*Case 3*	*Case 4*
Dose of vitamin B_{12} (µg)	40	40	60	40
Vol. of urine:				
In 24 hr. before B_{12} injections	550	1300	900	1250
In 24 hr. immediately after B_{12} injections ..	500	1620	550	1300
In 24 hr. on other days	500–550	1000–1800	700–1000	870

The urine of these patients was collected before and after the days of the test, and no appreciable change was found.

ORIGIN OF PLACENTAL TROPHOBLAST

SIR,—This letter is designed as a critique of last year's article by Dr. Gordon.[2]

Dr. Gordon's article is to the uninitiated a carefully worked out and apparently scholarly argument in support of his theory that the trophoblast is derived from "the follicle cells that surround the ovum when it leaves the ovary." It is this very care with which his case has been made that makes the article dangerously deceptive. So few people have had first-hand experience with this special field of embryonic development that it seems to me rather likely that many may be led to give undue credence to Dr. Gordon's opinion, not realising that he gives absolutely no direct evidence in support of this biologically bizarre concept, and that he totally ignores very ample direct evidence that the trophoblast is a product of the embryo.

Dr. Gordon cites an impressive list of 103 references from which he gleans his "evidence." It is worth noticing that his name is not among these. Many of these articles have a bearing on the subject much less direct than Darwin's concatenation related in the old story of the failure of the clover-seed crop in a certain county due to the death of two old maids who kept numerous cats. In that case the chain of dependent influences leading from their cats, through the mice, the bumble bees, and finally to the pollination of the clover, is at least logical in theory. Yet among the articles he cites are dozens containing direct anatomical evidence for the origin of the trophoblast from the outer layer of the blastodermic vesicle. It is not necessary for me to cite individual papers or particular figures in support of this accepted developmental fact. It is enough to point out that early in the study of the phenomena of this period of development there was indeed some confusion, there being those (notably Hubrecht) who at that time held that the trophoblast was of maternal origin. As more information, both anatomical and experimental, accumulated, syncytia of maternal origin have been distinguished from the trophoblastic syncytium, and the whole matter has been cleared up. My own observations on a rather large amount of comparative material have in every case supported the embryonic origin of the trophoblast, and at this point I feel impelled to ask (as must many others of my scientific colleagues) by what system of thinking—it cannot be called logic—Gordon can justify pulling out of my publications, and of those of others, such as Heuser and Streeter, inconsequential and irrelevant details to be inflated by him beyond all reason, while at the same time he ignores the great mass of important and pertinent direct evidence for embryonic origin of the trophoblast.

Dr. Gordon's introductory paragraph states: "The purpose of this paper is to present for discussion and experiment an entirely unorthodox view of the origin of the main portion of the placental trophoblast—namely, that it is formed from the follicle cells that surround the ovum when it leaves the ovary." Gordon defines trophoblast as "the invasive element of many mammalian placentæ, including the cytotrophoblast of Langhans and the syncytium." He lists twelve lines of evidence which he himself characterises as "indirect," but nowhere presents the direct evidence for fœtal origin of the invasive trophoblast—evidence which is to be found abundantly in practically every description of implantation and placenta formation in any mammal which has an endotheliochorial or hemochorial form of placentation.

It is certainly not a productive scientific endeavour to spend time analysing Gordon's indirect "lines of evidence," but it may be necessary lest I be accused of ignoring Gordon's evidence in the same way that I have accused him of ignoring the evidence of "orthodox" embryologists. I shall proceed briefly to analyse his twelve points.

1. "The production by follicle and trophoblast of similar hormones." Œstrogens and gonadotrophins are obtainable from a wide variety of biologic sources completely unrelated to one another.

2. "The hydatidiform mole and the independence of the trophoblast." There is no conceivable reason why the trophoblast should not grow independently of the embryo, since it is the absorptive layer of the fœtal membranes.

3. "Chorionepithelioma and its independence of a fertilised ovum." There is just as much reason to believe that chorionepitheliomas arise "independent" of follicular epithelium as of an ovum. Their origin in most cases is a mystery. They occur also in the male.

4. "The ovarian reaction in hydatidiform mole and chorionepithelioma." Gordon seems to think that the high incidence of multiple ovarian lutein cysts indicates that the same stimulus is causing both lutein-cyst formation and the abnormal trophoblastic growth, and argues that this similarity of response indicates the common origin of cysts and trophoblastic tumour from follicular epithelium. This entirely unjustified assumption is characteristic of all of Gordon's arguments. A more probable relationship between the tumour and the ovarian cysts is that the latter are evidence of the secretion of gonadotrophins by the tumour. Gonadotrophins cannot be extracted from tumours, but can be recovered from cultures of trophoblast.

5. "The inherent property of granulosa cells to proliferate as tumorous tissue." Granulosa cells are essentially embryonic and proliferative in character and no more prone to hyperplasia than many other tissues. One might as well argue that trophoblast is derived from endometrial stroma because the latter proliferates.

6. "The phylogeny of the graafian follicle." Ericulus, an insectivorous mammal of the family Centetidæ, has been shown by Strauss to have a highly developed "invasive" trophoblast forming a discoid hemochorial placenta, yet its ovarian follicles have no cavities; in fact the sperm penetrate the

2. Gordon, I. *Ibid*, i, 807.

By this method the ulcer can be skin-grafted in such a way that the graft cannot slip or move about while the patient is ambulatory. This technique is quite simple, does not require a general anæsthetic and hospitalisation, and—most important—allows the patient to carry on with her household duties. However, as I have already suggested, this technique should not be applied in all cases. The vast majority of ulcers will heal with conservative and medical treatment when attention is paid to the underlying causes.

ALBUMIN-ACTIVE ANTISERA IN RHESUS TYPING

SIR,—I feel that Dr. Stirk's article last week calls for some comment. The burden of his contribution would seem to be that he regards it as unnecessary to define the nature of the antibody present in his grouping serum, or to absorb out the anti-A or anti-B agglutinins. In support of these contentions he cites reasonable agreement of his distribution of positive and negative reactors in a "population" of 206 with the known incidence of D and d.

The use of incomplete anti-Rh sera for routine grouping is now accepted as standard practice in most laboratories which perform this work on a large scale. Dr. Stirk's methods, rather than economising in serum, would appear to do the reverse in so far as the quantity of blood he removes from his donors is very small and the use of two sera for each test doubles the quantity used.

The shortage of anti-Rh serum of any type is severe enough to make essential the most efficient use of all the available material. This can only be done by removing a generous quantity from the donor, replacing it if necessary by a transfusion of homologous blood; by accurately identifying the antibody; and by careful absorption of anti-A or anti-B with the appropriate cells.

As an example of what may be done in this direction, this laboratory, in addition to being self-sufficient for all grouping serum, has in the past year supplied the Regional Blood Transfusion Service with several hundred ml. of each anti-C, anti-E, and anti-c. Our consumption of serum is heavy, involving the performance of an average of over six thousand tests per year and the supplying of serum to three subsidiary laboratories. The area which we serve has approximately the same population as the Wolverhampton group—i.e., 500,000.

CONGENITAL ŒSOPHAGEAL ATRESIA

SIR,—Dr. Donnelly, in his article of April 8, paints an unnecessarily gloomy picture of the prognosis in congenital atresia of the œsophagus with tracheo-œsophageal fistula.

I have recently reported on 8 cases, with 2 completely successful results [1]; and since my article went to press Mr. David Adler, the thoracic surgeon, has seen 4 more cases in Johannesburg. Of these further 4, 1 was not thought suitable for operation owing to other congenital abnormalities. Another had been given barium by a radiologist and, having severe bronchopneumonia, was a very bad risk; operation was performed but the child survived for only eight hours. The remaining 2 were successfully operated on, and left hospital feeding normally.

These results are very encouraging, and a review of the American literature is even more so. Dr. Donnelly, I think, gives a false impression of the best American views on the subject. He states that Ladd and Swenson [2] favoured the multiple-stage operation. Yet Swenson [3] reports that of 20 cases, 15 were treated by primary œsophageal anastomosis with 14 successes; the remaining 5, in which the patent portions of the œsophagus were too far apart to allow the ideal of direct anastomosis to be achieved, were as a second-best measure treated by multiple-stage operations, only 2 surviving.

Dr. Donnelly does not mention the type of anæsthesia in his series. I am convinced—and so apparently is Swenson—that general anæsthesia with cyclopropane gives the best operating conditions and the best chances of successful operation, and therefore of survival.

Both Dr. Donnelly and I plead in our articles for early diagnosis, but I feel that such a plea is only likely to receive the attention it deserves if the general practitioners and midwives who must make this early diagnosis, are convinced, as I am, that the prognosis is far from exceedingly bad.

Johannesburg, South Africa. F. W. ROBERTS

STREPTOMYCIN IN ACUTE MILIARY TUBERCULOSIS

SIR,—Two points raised in the Medical Research Council's report, published in your issue of May 6, are in notable contrast to our findings in Sheffield. They concern the significance and incidence of choroidal tubercles and the prognosis in children under two years of age.

The report states: "there is no record of choroidal tubercles having been seen in any of these cases on admission." They were found subsequently in 5 out of 25 cases (20%). Choroidal tubercles were found in 13 of our 22 cases (59%), and they were seen on admission in all those who subsequently developed meningitis.

On the basis of findings in 5 cases, the report regards the finding of choroidal tubercles as a danger signal that meningitis is likely to develop. In our series of 22 cases, choroidal tubercles were found on admission in 7 out of 11 of those who later developed meningitis and in 6 of the 11 who did not subsequently develop it.

We would add that in our series of 175 cases with miliary and/or meningeal tuberculosis in no case have we found choroidal tubercles in meningitis without miliary tuberculosis, when proper search was made for miliary spread by histological examination.[1] Bernard et al.[2] made the same observation. The finding of choroidal tubercles in a case of meningitis is, therefore, taken by us to denote miliary spread whether or not the radiograph of the chest shows it. In the one case of uncomplicated meningitis previously described by us[3] in which choroidal tubercles were found, it was subsequently shown by further histological examination that miliary tuberculosis was in fact present.

In no case have we been able to observe the disappearance of choroidal tubercles. One of the case-reports (case 23) in the M.R.C. series implies that this may occur, by saying that "choroidal tubercles were still present."

The second point in which our findings differ from those of this series is the prognosis in children under two years of age. All 3 of the Medical Research Council's cases died. Of our cases, 12 fell into this age-group. 6 developed meningitis, and 4 of these are alive after 30, 28, 24, and 11 months of observation. 6 did not develop meningitis, and 5 of these are alive after 30, 26, 23, 21, and 5 months of observation. We think that this is important, because there are still many who believe that the prognosis in the younger age-group is almost hopeless.

We feel strongly that if good results are to be obtained in meningitis developing during the course of miliary

BLOOD DESTRUCTION AND CEREBRAL DAMAGE IN HÆMOLYTIC DISEASE OF THE NEWBORN

SIR,—Discussing exchange transfusion in hæmolytic disease of the newborn, Mollison and Cutbush[1] wrote:

> "Thus at first sight it seems likely that the only way in which the value of exchange transfusion could be proved decisively would be by applying it to alternate cases in competition with, for example, simple transfusion. . . . It may not be necessary to attempt statistical proof if further evidence can be collected to show that the tissue damage in hæmolytic disease is in some way related to blood destruction . . ."

We believe we have succeeded in getting this proof, at least as regards cerebral damage.

It was postulated that in kernicterus the yellow discoloration of the ganglion cells is a secondary effect, because bilirubin is said to enter ganglion cells only if they are already damaged. However, Goldmann[2] showed that ganglion cells are not impenetrable by dyes but are protected against such penetration by the retention of dyes in the endothelial cells of the cerebral vessels, which are the only blood-vessels possessing this power. Trypan-blue, even in high concentration, does not penetrate from the blood-stream into the nerve tissue. The intrathecal injection of the same stain, however, causes symptoms of serious irritation and discoloration of the nerve-cells near the surface of the brain. These investigations have been repeated and confirmed by Spatz,[3] who is convinced that bilirubin acts in exactly the same way.

In hæmolytic disease of the newborn there is capillary damage, which is extreme in fœtal hydrops, and in most cases of icterus gravis slight œdema can also be found. Cerebral œdema is always present in kernicterus.[4] Therefore the endothelial cells of the cerebral capillaries cannot fulfil their protective function completely. In this way bilirubin can penetrate from the blood-stream into the nerve tissue in icterus gravis. In congenital atresia of the bile-ducts the endothelial cells are intact and bilirubin cannot leave the blood-stream and penetrate into the brain. The question arises whether bilirubin is harmful to nerve tissue or not.

We brought bilirubin into contact with living nerve tissue and noted the results. The injection of a highly concentrated solution of bilirubin into the carotid arteries of rabbits did not cause a yellow discoloration of the brain; this confirmed the results of Goldmann[2] and Spatz.[3] However, a cerebral icterus can be caused by an infusion into the carotid artery lasting about 30 minutes, as follows:

Rabbit no.	*Infusion* *	*Fate of rabbit*	*Cerebral icterus*
1	5% glucose	Survived	–
2	Bilirubin (40 mg. per 100 ml.)	,,	–
3	,, (60 ,, ,, ,,)	,,	–
4	,, (75 ,, ,, ,,) and histamine	,,	–
5	Bilirubin (75 mg. per 100 ml.) and histamine	Died in 4 hr.	++
6	Bilirubin (100 mg. per 100 ml.)	Survived	–
7	,, (100 ,, ,, ,,)	,,	Trace
8	,, (100 ,, ,, ,,)	Died in 3 hr.	++
9	,, (125 ,, ,, ,,)	Died shortly after infusion	+++
10	,, (150 ,, ,, ,,)	Died at end of infusion	+++
11	,, (150 ,, ,, ,,)	Died at end of infusion	+++
12	,, (150 ,, ,, ,,)	Died at end of infusion	++++

* The amount of the infusion was 60 ml. per kg. of body-weight in rabbit no. 5. In all the other rabbits the amount was 40 ml. per kg. Bilirubin was given in 5% glucose.

It will be seen that a very high concentration of bilirubin was needed to produce cerebral icterus in these experiments, but in naturally occurring icterus gravis there may be as much as 40 mg. of bilirubin per 100 ml. passing through the brain for days (not for only 30 minutes as in our experiments). In addition to this is the capillary lesion, the cause of which is not exactly known. Our experiments suggest that the penetration of bilirubin into the nerve tissue must have disastrous consequences in the human body also; thus the bad prognosis of kernicterus is completely explained. Direct cerebral damage by the antigen, or the effects of liver toxins on the brain, however, are not ruled out by our results; but there is no need to invoke them in order to explain the cerebral damage in kernicterus.

The conclusion to be drawn as regards therapy is that early exchange transfusion should be given in all severe cases of icterus gravis, without testing its efficacy by giving it only in alternate cases, since it is unnecessary to prove its effect in this way. Only by exchange transfusion can hæmolysis be stopped to any great extent, and the accumulation of end-products of hæmolysis be prevented. Mollison and Cutbush[5] have published a method of assessing the severity of a case of hæmolytic disease of the newborn and so determining whether an exchange transfusion is necessary or not.

THE VOLE

SIR,—The lower orders do not often have the opportunity of reading THE LANCET. Our conditions of life are all against easy access to the medical journals. I am in an exceptional position owing to the courtesy of a man friend of mine who is himself smarting under the insult of having his photograph taken by a foreign journalist who was so misguided as to think his initials were H. G.

There appears on p. 797 of your issue of April 29 a libellous photograph of me. The libel attaches not to the compromising attitude in which the photograph was taken, but to the fact that it is an excellent likeness of *Sorex araneus*—the shrew. Now Sorex is a low fellow, no relation of mine and wholly undeserving of any mention in the medical press, whereas my social and academic distinction is well known to many of your readers—and I hoped to your good self. I should be obliged if you will make a public apology as soon as possible.

MICROTUS AGRESTIS.

P.A.S.

SIR,—I have read the letter of May 6 by Dr. Carstensen and Dr. Andersen with great interest, not only because the observations reported are important to the use of *p*-aminosalicylic acid (P.A.S.) in tuberculosis, but also because they confirm observations on a small number of cases reported to the Tuberculosis Society of Scotland in January, 1949.[6]

At that time only 9 patients had been observed who had completed three months' treatment with P.A.S. I stated that in my comparatively limited experience, maximum benefit was usually obtained after about four weeks, and that 4 of the patients began to show evidence of deterioration after ten weeks' treatment. At the suggestion of Prof. Charles Cameron, the number of bacilli in direct smears and the rate of growth of sputum cultures on Loewenstein-Jensen medium was recorded. 5 cases became negative, even on cultural examination, at some stage during treatment. In 1 instance —a case of chronic disseminating tuberculosis—the sputum remained negative for sixteen weeks, after which I lost trace of the patient. In the other 4 cases the sputum became negative on culture—at the fifth week in 3 cases, and at the tenth week in the other—but became positive again at ten,

ovarian tissues and the eggs are fertilised within the follicles. The pronuclear stage of the eggs is shed into the oviduct by gradual dispersion of the overlying follicle cells, and there is no remaining corona radiata to furnish the germ of the trophoblast according to Gordon's theory.

7. "The analogy of the functions of the follicle cells and the trophoblast." Gordon's contention here is that since the follicular epithelium functions as the nutritive membrane for the ovarian ovum, why should it not have been utilised as the nutritive membrane for the uterine embryo? By the same reasoning it would make just as much sense to argue that the mammary epithelium is derived from trophoblast.

8. "Ontogeny and phylogeny." Probably Gordon's confusion here results from separating in his mind the entity of trophoblast from that of chorionic ectoderm. Hubrecht was confused on this point. All available evidence (and there is much more than Hubrecht had forty years ago, or than Gordon seems aware of at present) shows that the trophoblast is the outer layer of the blastocyst and chorionic vesicle. Calling the outer layer of the blastocyst and the chorionic vesicle before invasive properties appear in it "chorionic ectoderm," and after invasiveness occurs "trophoblast," is quite all right if one feels anything in the way of understanding is gained by so doing. However, this should never be promoted to the point that beginning students or other inexperienced people forget that the invasive chorionic ectoderm or trophoblast is derived from the non-invasive type, and that in most cases the two are directly continuous with each other at the placental margins, where indeed all transitional stages between the two conditions can be seen by anyone who cares to look.

9. "The histological dissimilarity of the cytotrophoblast and the chorionic epithelium in man." There is considerable difference between the cells of the various layers of the epidermis, yet this is not thought of as evidence that they have different origins.

10. "The similarity of granulosa cells and cytotrophoblast in culture." This argument of similarity of granulosa and trophoblast cells is too flimsy to warrant more than pointing out that there is much more similarity in appearance between syncytial trophoblast and syncytia formed from the uterine epithelium than there is between granulosa and trophoblast cells.

11. "The unusual placenta of the hyracoidea." Perhaps if Gordon had read Wislocki's 1940 paper on the placenta of Hyrax he would have been less impressed by the tendency of the mesoderm to separate from the trophoblast.

12. "The transplantation of tissues and the evidence of blood-groups." Gordon believes that if the trophoblast were of fœtal origin instead of maternal it should set up an immune body reaction with the mother or host tissues. To this one can ask, what difference would it make whether the fœtal-maternal contact takes place at the trophoblast-decidua level or at the mesoderm-trophoblast level if the trophoblast really were maternal tissue? We just do not know enough about these antigen-antibody reactions in the complex situations arising in placental development to use them as evidence in such a matter.

In a section entitled "The Mechanism" Gordon purports "*to consider the observed facts* of the fate of cumulus cells and ovum in tube and uterus." These "facts" seem to add up to the following: cumulus cells are observed to fall away from the egg in the tube, but the descriptions of this falling away have in his opinion been "much exaggerated." The rest of this section is both irrelevant and conjectural. In fact even the one statement of relevant fact above, is presumptive also.

The inadequacy of the evidence for Gordon's hypothesis is emphasised by the nature of the items which he has attempted to marshal in support of it, such as Heuser and Streeter's "slipped nuclei" and my own admittedly highly theoretical suppositions regarding the evolution of the ungulate type of epitheliochorial placenta. In another section entitled "Deductions, Placental Gonadotrophin" Gordon builds up what might be called a pseudo-rationale of treatment of reproductive dysfunctions, &c., based on his assumption of follicular origin of trophoblast and endometrial origin of placental gonadotrophin. Also he postulates infertility due to failure of egg and follicle cells to reunite. It is certainly a waste of many things to carry such flights of imagination into print without even a sound major premise.

Some of the experiments suggested to test this hypothesis would be perhaps interesting and valuable, but certainly would not disprove the often observed fact of the fœtal origin of the trophoblast. There is no dearth of problems for research on the biology both of the trophoblast and of the follicular epithelium. One might point out the value of one established fact, such as the fœtal origin of the trophoblast, in contrast with an armchair "research" such as the article just reviewed, which has wasted much of both your time and mine.

TUBERCULOSIS

SIR,—I take it that Dr. Reade, in his letter last week, is suggesting segregation of the open case of tuberculosis. Does he propose to use for this purpose our already inadequate quota of beds, or does he advocate the provision of special institutions? These unfortunate cases certainly present a most serious problem, but instead of demanding compulsory segregation we should rather devote our efforts to earlier diagnosis and to the eradication of sanatorium waiting-lists: these measures will ultimately do away with the problem of the open case.

HYPOTHERMIA WITH CHLORAMPHENICOL

SIR,—Squadron-Leader Briggs, in your issue of Jan. 21, described a case of typhoid fever in which, on the 5th day of treatment with chloramphenicol, the temperature fell to 95°F; the patient complained of feeling cold, and a coarse tremor of the hands and legs appeared. This observation prompts me to record my own experience of this curious phenomenon.

I was called in to see a Hindu man, aged 24, who had recently arrived from India and who gave a history of severe headache and pain in the back with continuous fever for the past week. He had been inoculated with T.A.B. vaccine about a year before.

The patient looked toxic; his temperature was 103°F. He had a dicrotic pulse with a rate of 100 per min. Blood-pressure 120/70 mm. Hg. His tongue was coated. The spleen was just palpable. Rose spots were clearly discernible on his abdomen and chest. Occasional rhonchi were heard on both sides of the chest.

Typhoid fever was diagnosed clinically. Blood was taken for a Widal reaction; and this proved positive against *Salmonella typhi* (*O* 1/500 and *H* 1/50).

Treatment was commenced with chloramphenicol. An initial dose of 1 g. was followed by 0·25 g. 2-hourly. For 72 hours the temperature remained above 103°F; it then started to fall gradually, and 80 hours after the start of treatment it was 100·5°F. The patient's general condition improved considerably during this period, and the toxæmia was much less.

Then, 90 hours after the start of treatment, the temperature suddenly dropped to 94·5°F; the patient became very restless and complained of a chilly sensation. The patient looked anxious; he was not sweating, and his pulse was of good volume (the rate being 80 per min.); blood-pressure 115/70 mm. Hg. No tremor was detected.

Chloramphenicol was stopped immediately. The patient's condition gradually improved, and within the next few hours the temperature gradually rose to 98°F, and the symptoms slowly disappeared. No more chloramphenicol was administered. From then on, the temperature remained within normal limits and the patient made an uneventful and complete recovery.

Further observations will be required to ascertain whether hypothermia of this sort is a toxic effect of the drug, and, if so, what effect it has on the general course of the disease.

Nairobi, Kenya.

B. P. ARYA.

SOME LIMITATIONS OF PSYCHIATRY

SIR,—This correspondence has been interesting. In his letter last week Dr. Watts says: "Dr. Haldane is biased by the type of material he is seeing, and he is obviously not acquainted with psychiatry at general-practice level," where cases are seen in their early stages.

It seems to me that there is much truth in this judgment, which requires the establishment of "an intelligent relationship between the general and psychological physician." The truth is that the psychological physicians do not make any such relationship easy. Some of them hide behind an obscurantist screen: "if you haven't had three years' analysis you can't understand this patient." Others put their trust in machines: "Ah! we will give him E.C.T., and if this does not cure him he is incurable." No wonder that G.P.s are wont to say that they know nothing about psychiatry. It discourages the early approach that the ideal G.P. would make to the patient. That is to say, he would take matters in hand when the patient's anorexia begins to show itself; he would take an interest in the only son who is being spoiled by his mother; he would interest himself in the girl with a bad heredity who was distressing her parents by unsuitable friendships; he would concern himself with the youth who refused to take a job offered him; and he would realise that a lad of 18 with a constant nasal discharge is liable to be a life-long neurasthenic or even schizophrenic.

In conclusion, my submission is that as long as psychiatrists show so little practical interest in early and synergic ætiology, so long will the G.P.s feel justified in ignoring these early factors in a full-blown psychosis.

Harrow-on-the-Hill. H. CRICHTON-MILLER.

SIR,—In my article of April 29 I appear to have misled readers by my use of the word "placebo." Seemingly to a physician the term connotes a medicine of no therapeutic value, whereas I, as a psychiatrist, regard a properly used placebo as of real, though strictly limited, usefulness. I characterised as a "psychiatric placebo" the procedure of simply assuring a patient that he has nothing physically amiss and that his bodily health is excellent, without attempting to seek out and deal with any underlying tensions.

In my summing up, I used the word "placebo" to indicate treatment that does not attempt some readjustment of character drives. This usage was injudicious and confusing, because what may be a mere placebo in one situation may be adequate treatment in another. An aspirin tablet may be a placebo of sorts in an attack of migraine, yet quite effective for an ordinary headache.

The boundaries of neurosis are ill-defined. Some of us are more, and some of us are less, neurotic. With most of us, under reasonably favourable environmental conditions our neurosis neither expresses itself in serious symptoms, nor leads to behaviour disastrous to ourselves or quite intolerable to those who have to live with us, nor seriously reduces our working capacity, nor completely robs us of the joy of life. A temporary worsening of conditions, may lead to the appearance or intensification of one or more of these effects of neurosis. It is chiefly when the effect takes the form of symptoms that a doctor is likely to be consulted. Then simple suppression of the symptoms is likely to be accompanied by intensification of some of these other effects. The whole may well return to its usual state as and when environmental conditions improve again. A minor degree of neurotic suffering from time to time is the life-long lot of many in our present culture.

The exacerbations of a not too severe neurosis may often be relieved by methods which produce no enduring change in the neurotic personality. Reassurance and persuasion, for example, accompanied by redirection of the patient's efforts and attention towards some of the immediate sources of his mental stress, may succeed, especially if he is able actively to improve his environmental situation. Treatment of this order should be within the scope of the general physician, and indeed I do not doubt that he may often do the job better than the psychiatric specialist. Nothing could be more at variance with my outlook than to regard such relief of suffering as "not worth while." This would indeed be an odd standpoint for any doctor. At the same time there are some cases where one feels it best to leave some symptoms undisturbed.

My main argument was that the radical treatment of a serious neurosis—i.e., treatment that must be provided by a highly trained specialist—is of a different nature, cannot be accomplished by a few talks, and requires much time, effort, and persistence as well as special skill and intricate understanding; that this is due to the nature of such disorders; and furthermore that there are many such sufferers at present to whom such treatment is not applicable, or who would require more than is now available, and for whom other methods at our disposal are not adequate.

As for my supposed pessimism, of the three cases quoted the first two were accepted for treatment. The over-optimistic attempt to draw the third into therapy failed. Direct removal of his symptom, had this been possible, might in this case quite possibly have precipitated a paranoid psychosis. I cannot regard as pessimism the recognition of the conditions necessary for the attainment of aims.

THE OPEN WOUND IN TRAUMA

SIR,—I would be grateful for some space to comment on Mr. Essex-Lopresti's assertion (April 22) that early closure of accidental wounds, including war wounds, is the main factor on which the success of treatment depends. He affirms that "conditions in the early years of the first world war . . . were such that primary closure was not attempted, and the dire consequences of grave infection were again evident. . . ." This is not exact. Primary suture had been attempted, and until it was abandoned results did not improve. The change in the surgeon's attitude was due to the recognition that it was wound excision and not primary suture which conditioned the future of the patient. Mr. Essex-Lopresti's belief is reasserted in stating that the publication in 1939 of my work on this subject encouraged the abandonment of the technique which had proved successful in the last two years of the first world war. In support of his views he mentions the American surgeon, Dr. Cleveland, who, in 1946, wrote that "the closed plaster technique of treatment of compound fractures . . . invites infection of bone and soft tissue and healing ensues slowly by second intention, with massive granulations which developed into scar tissue." Evidently both Dr. Cleveland and Mr. Essex-Lopresti refer to the Winnett Orr technique of wide drainage "to prevent the pus from accumulating" and to encourage granulation "from the bottom." Further, Mr. Essex-Lopresti attributes to my method the 10 cases of his series which became infected after being left open and also the 4 which developed septic complications after primary suture and were subsequently treated in the Winnett Orr way. All these cases—all failures—he graciously attributes to my technique.

His paper contains much that is good. I may mention at random, its emphasis on the importance of wound excision which, I am glad to know, does not now need detailed recapitulation "as it is so well known." *Also* twelve, fourteen, and fifteen weeks respectively, the patients still being under treatment. In 3 of the 4 cases where the sputum remained positive throughout, the number of tubercle bacilli per high-power field decreased progressively up to the eighth week and began to increase greatly at the tenth week. In all 4 cases the rate of growth of culture on Loewenstein-Jensen medium became steadily slower up to the eighth or tenth week, but by the fourteenth week had returned practically to the rate observed before treatment was started. Before treatment, growth was observed at 14, 18, 18, and 24 days in these cases, but at the eighth or tenth week no growth was observed until 61, 45, 112, and 70 days, respectively. I concluded that these observations suggested that P.A.S.-resistant organisms might be produced, or that the organisms had been trained into withstanding previously lethal doses of the drug.

The dosage (15 g. daily) was similar to that used by Dr. Carstensen and Dr. Andersen. In one case not previously reported, before treatment, growth was obtained 24 days after sowing the culture. At the eighth week of treatment the number of bacilli had fallen from 30 to 4 per high-power field, and no growth was obtained until 117 days after sowing the culture. Only three colonies were obtained, but the culture, when inoculated into a guineapig, produced gross disseminated tuberculosis. At the fifteenth week of treatment a luxuriant growth was obtained after 26 days.

Dr. Carstensen and Dr. Andersen add that the clinical course of the disease agrees in most instances with the sensitivity of the bacilli to P.A.S. If my observations on the change in the rate of growth of tubercle bacilli in patients treated with P.A.S., indicate the development of P.A.S.-resistance, my experience was similar. I look forward to a detailed report on this important aspect of treatment with P.A.S.

GENERAL PRACTICE

SIR,—All cures prescribed for the present ills of general practice (including that of Dr. Collings) urge that more partnerships and group practices, and the use of health centres, must be an early part of the treatment.

There are many general practitioners, however, who have deliberately chosen to work alone, not only by geographical circumstance but in towns and cities as well. These lone practitioners ranked high even in Dr. Collings's short survey of good and bad practices. There are always dangers in isolation, and perhaps in undue possessiveness of patients; but there are advantages too on both sides.

Patients have selected single practitioners just because of the near certainty of seeing the same doctor every time. This certainty can mean a great deal after the number of personalities and the variants of opinion and instruction experienced at hospitals.

The doctor may have the cumulative experience of three generations of many families seen in all their emergencies over a stretch of years; to many this outweighs the uncertainty of ever being really free from calls on their time.

Is a reasonably well-equipped consulting-room and waiting-room so inferior to accommodation in a glittering health centre of the future? Such practitioners often have strong attachments to their own premises, but surely the equipment needed is not so very elaborate and costly, nor so difficult in upkeep.

Single practitioners are rarely at their best in partnership; they often run a trifle uneasily in double harness. Independence and strong identification with patients may be a strength in isolation but a source of friction in partnership.

Is there not a risk that single-doctor practices with surgery accommodation in ordinary dwelling-houses may become slightly downgraded in the eyes of the public in the future? Given sufficient contacts with colleagues and with hospitals, such practitioners have by their very nature contributed much that is best in real family practice and can surely do so in the future too.

London, W.2.
ANNIS GILLIE.

SIR,—Research in general practice is hardly touched on in the Collings report, and it is indeed usually not regarded as a function of the general practitioner.

A little reflection will demonstrate the unwisdom of this view. As a general practitioner, I make about 10,000–12,000 visits and consultations each year, and allowing on the average three visits or consultations per illness I evidently see about 3500 illnesses yearly. In 1949, I referred to hospital for advice or treatment 178 patients—a figure which represents roughly 5% of all the illnesses I see—while the other 95% were dealt with entirely at the "general-practitioner level." The 95% is little spoken of in the medical literature, and comparatively little is known about this largest part of illness, since general practice, alone among the branches of medicine, is apparently absolved from the responsibility of carrying out research and advancing knowledge of the clinical material it deals with. The complaint so often heard, that general practice is just hack-work and the practitioner a glorified sorting officer, is due precisely to this lack of research activity, which is, or should be, part of the job.

The factors inhibiting the general practitioner from research work are many, and so strong that few have made much progress at it. This indeed is little to be wondered at, for it is a difficult discipline, without material incentive as things stand. Merit awards are not for the general practitioner, who, if successful at research, can only hope to increase his income by enlarging his practice at the expense of his limited research time. There is, of course, no reason to suppose that success or failure at research will lead to any substantial change in the size of a man's practice. That is determined by quite other considerations.

Lowestoft.
N. B. EASTWOOD.

SIR,—Dr. Pinsent's article last week focuses attention on one eminently practicable solution to the problem of the overworked general practitioner—i.e., to reinforce practitioners with nurses. If this proposal is to be successfully implemented, however, it is necessary to convince the public (including members of executive councils) of its value.

Arising out of a conference organised by the Royal College of Nursing in January, 1949, my authority put three proposals to the local executive council:

1. That general practitioners be given facilities for running antenatal clinics for their own patients on local-authority premises, and be given the services of a nurse at such clinics.
2. That facilities for minor surgery, with the necessary nursing help, be provided for general practitioners in local-authority clinics.
3. That health visitors be available to help general practitioners in their practice. (This envisaged duties such as Dr. Pinsent outlines in his article.)

The first two recommendations were approved by the executive council, but the third was disapproved, because the example cited was an unfortunate one—a measles epidemic when the practitioners would pay all first visits and the nurse might report progress in selected cases at subsequent visits. The principle of nurses to help overworked practitioners with visiting was therefore not accepted, but:

"We fall to rise—
Are baffled to fight better—
Sleep to wake."

SOME LIMITATIONS OF PSYCHIATRY

Sir,—This correspondence has been interesting. In his letter last week Dr. Watts says: "Dr. Haldane is biased by the type of material he is seeing, and he is obviously not acquainted with psychiatry at general-practice level," where cases are seen in their early stages.

It seems to me that there is much truth in this judgment, which requires the establishment of "an intelligent relationship between the general and psychological physician." The truth is that the psychological physicians do not make any such relationship easy. Some of them hide behind an obscurantist screen: "if you haven't had three years' analysis you can't understand this patient." Others put their trust in machines: "Ah! we will give him E.C.T., and if this does not cure him he is incurable." No wonder that G.P.s are wont to say that they know nothing about psychiatry. It discourages the early approach that the ideal G.P. would make to the patient. That is to say, he would take matters in hand when the patient's anorexia begins to show itself; he would take an interest in the only son who is being spoiled by his mother; he would interest himself in the girl with a bad heredity who was distressing her parents by unsuitable friendships; he would concern himself with the youth who refused to take a job offered him; and he would realise that a lad of 18 with a constant nasal discharge is liable to be a life-long neurasthenic or even schizophrenic.

In conclusion, my submission is that as long as psychiatrists show so little practical interest in early and synergic ætiology, so long will the G.P.s feel justified in ignoring these early factors in a full-blown psychosis.

Harrow-on-the-Hill.   H. Crichton-Miller.

Sir,—In my article of April 29 I appear to have misled readers by my use of the word "placebo." Seemingly to a physician the term connotes a medicine of no therapeutic value, whereas I, as a psychiatrist, regard a properly used placebo as of real, though strictly limited, usefulness. I characterised as a "psychiatric placebo" the procedure of simply assuring a patient that he has nothing physically amiss and that his bodily health is excellent, without attempting to seek out and deal with any underlying tensions.

In my summing up, I used the word "placebo" to indicate treatment that does not attempt some readjustment of character drives. This usage was injudicious and confusing, because what may be a mere placebo in one situation may be adequate treatment in another. An aspirin tablet may be a placebo of sorts in an attack of migraine, yet quite effective for an ordinary headache.

The boundaries of neurosis are ill-defined. Some of us are more, and some of us are less, neurotic. With most of us, under reasonably favourable environmental conditions our neurosis neither expresses itself in serious symptoms, nor leads to behaviour disastrous to ourselves or quite intolerable to those who have to live with us, nor seriously reduces our working capacity, nor completely robs us of the joy of life. A temporary worsening of conditions, may lead to the appearance or intensification of one or more of these effects of neurosis. It is chiefly when the effect takes the form of symptoms that a doctor is likely to be consulted. Then simple suppression of the symptoms is likely to be accompanied by intensification of some of these other effects. The whole may well return to its usual state as and when environmental conditions improve again. A minor degree of neurotic suffering from time to time is the life-long lot of many in our present culture.

The exacerbations of a not too severe neurosis may often be relieved by methods which produce no enduring change in the neurotic personality. Reassurance and persuasion, for example, accompanied by redirection of the patient's efforts and attention towards some of the immediate sources of his mental stress, may succeed, especially if he is able actively to improve his environmental situation. Treatment of this order should be within the scope of the general physician, and indeed I do not doubt that he may often do the job better than the psychiatric specialist. Nothing could be more at variance with my outlook than to regard such relief of suffering as "not worth while." This would indeed be an odd standpoint for any doctor. At the same time there are some cases where one feels it best to leave some symptoms undisturbed.

My main argument was that the radical treatment of a serious neurosis—i.e., treatment that must be provided by a highly trained specialist—is of a different nature, cannot be accomplished by a few talks, and requires much time, effort, and persistence as well as special skill and intricate understanding; that this is due to the nature of such disorders; and furthermore that there are many such sufferers at present to whom such treatment is not applicable, or who would require more than is now available, and for whom other methods at our disposal are not adequate.

As for my supposed pessimism, of the three cases quoted the first two were accepted for treatment. The over-optimistic attempt to draw the third into therapy failed. Direct removal of his symptom, had this been possible, might in this case quite possibly have precipitated a paranoid psychosis. I cannot regard as pessimism the recognition of the conditions necessary for the attainment of aims.

West Middlesex Hospital,
Isleworth.   F. P. Haldane.

THE OPEN WOUND IN TRAUMA

Sir,—I would be grateful for some space to comment on Mr. Essex-Lopresti's assertion (April 22) that early closure of accidental wounds, including war wounds, is the main factor on which the success of treatment depends. He affirms that "conditions in the early years of the first world war . . . were such that primary closure was not attempted, and the dire consequences of grave infection were again evident. . . ." This is not exact. Primary suture had been attempted, and until it was abandoned results did not improve. The change in the surgeon's attitude was due to the recognition that it was wound excision and not primary suture which conditioned the future of the patient. Mr. Essex-Lopresti's belief is reasserted in stating that the publication in 1939 of my work on this subject encouraged the abandonment of the technique which had proved successful in the last two years of the first world war. In support of his views he mentions the American surgeon, Dr. Cleveland, who, in 1946, wrote that "the closed plaster technique of treatment of compound fractures . . . invites infection of bone and soft tissue and healing ensues slowly by second intention, with massive granulations which developed into scar tissue." Evidently both Dr. Cleveland and Mr. Essex-Lopresti refer to the Winnett Orr technique of wide drainage "to prevent the pus from accumulating" and to encourage granulation "from the bottom." Further, Mr. Essex-Lopresti attributes to my method the 10 cases of his series which became infected after being left open and also the 4 which developed septic complications after primary suture and were subsequently treated in the Winnett Orr way. All these cases—all failures—he graciously attributes to my technique.

His paper contains much that is good. I may mention at random, its emphasis on the importance of wound excision which, I am glad to know, does not now need detailed recapitulation "as it is so well known." Also excellent are those remarks referring to the abolition of dead spaces and prevention of post-traumatic œdema by external pressure which, he says, was re-learned during the last war. Mention is made, even if it is inadequate, of the importance of immobilisation with plaster, the shortness of the reference to it perhaps being due to Mr. Essex-Lopresti's conviction that recapitulation is also unnecessary on this point. I must congratulate him on his emphasis on the importance of elevation of the part to prevent œdema. I am pleased to be in his company on this point also.

But in some other respects his article does not seem to me to be so sound. No-one would make me believe that accidental wounds such as those due to street or war injuries are not contaminated on reaching Mr. Essex-Lopresti and become systematically infected when left open in one of the best centres for traumatic surgery in the country. If he is right, we also must admit that the streets of Oxford—where wounds are contaminated on admission to hospital—are dirtier than those of Birmingham, and I do not think this is likely.

Closure of the wound is an ideal towards which any method based on biological principles, as that I propagated before and during the war, must tend. But it can only be achieved when all the factors contributing to success are present. To consider that not to close a wound is to depart from the right road is not only unjustified but dangerous. At the time of my campaign against primary suture in war wounds I personally reduced the size of the wounds I treated by immediately closing that part of the wound which had not suffered muscular damage. I immediately sutured, whenever possible, all the wounds of joints and also lacerations. In respect of skin-grafting I can only say that the first case treated in this country by the "Trueta" method in 1939 had skin-grafts placed on the wound. But I must insist that in muscular wounds, and in compound fractures, immediate suture is bound to cause many disasters when performed by surgeons less experienced than Mr. Essex-Lopresti and in centres less efficient than the Birmingham Accident Hospital. He recognises that no primary suture should be done in any wound in which vitality of the tissues is not clearly assured. In muscular wounds and compound fractures, who can guarantee that every bit of devitalised tissue has been removed at operation? I must humbly confess that after more than twenty years of intensive experience in treating accidental wounds I still have doubts in many cases about the accuracy of my excision. Mr. Essex-Lopresti seems to be faced with the same difficulty, for he says that "from the practical point of view, however, the problem (of wound excision) is not so simple; at the time of operation it is often extremely difficult to decide what tissues are viable." That is the main reason for my fidelity to the "five points technique" which I propagated at the beginning of the war.

Now that we have placed the right emphasis on wound excision and on the method by which it must be done, and now that no-one refers to it as a "decontaminating procedure" or a method to remove "the wound track," and now that no-one performs the "cancer excision" of previous times, suture is becoming less dangerous for a greater number of surgeons. Moreover, penicillin has enhanced the scope and safety of its performance. But to dedicate a paper to proclaim the wonders of primary suture is, I am afraid, the first indication of what will happen if a new conflagration falls upon us. It is this influence of Mr. Essex-Lopresti's writing which I would like to counteract. As to the way in which he refers to my work, I prefer to forget it. Fourteen years of strife have dissipated what I had of personal pride.

Wingfield-Morris Orthopædic Hospital,
Oxford.

J. TRUETA.

Notes and News

WAR AND PEACE

THE opening of the third World Health Assembly in Geneva on May 8 was marked by an incisive address from Mr. Trygve Lie, secretary-general of the United Nations Calling for greater assistance to the underdeveloped areas, he said: "The supreme challenge of the second half of the twentieth century—and especially of the next twenty years —is not expressed in the ideological and power conflict that monopolises the headlines today. The supreme challenge is presented by that great majority of the population of the world—over 1600 million—whose poverty, hunger, and insecurity must be substantially remedied if they are not to result in new and disastrous upheavals. Most of the people live in the so-called underdeveloped areas of the world, mainly in Asia and Africa. They are moving rapidly towards political equality. They will no longer accept the grinding poverty that has been their fate for centuries. We cannot meet this challenge successfully at the snail's pace of today. We cannot meet it by halfway measures. We cannot postpone it until a more convenient time. The challenge is here and now. Bold and creative action on a world-wide scale is required in order to bring about real improvements in the living conditions of these 1600 million people—improvements that will begin to be evident within the next five years and will have as their goal the doubling of living standards within twenty years in many of the poorer areas of the world. There is only one possible way of achieving so great an objective in so short a time. That is to use to their fullest capacity the universal machinery, resources, and experience of the specialised agencies and the United Nations. We are not doing that today. Our expanded programme of technical assistance for economic development and social welfare is a step in the right direction. But the allocation by the member governments of a far greater proportion than at present of their available resources in brain-power and money will be necessary. A United Nations programme to raise living standards can and should be planned and carried out on a non-political basis. It can and should be planned and carried out for the benefit of each one of the member States, without regard for the 'cold war.' If our programme of technical assistance for economic development can be expanded and applied to meet needs wherever they exist, I believe they can also make a substantial contribution toward reducing the tensions of the cold war and enlarging the area of common ground. It should not be forgotten that the technical-assistance programme was adopted unanimously by the General Assembly of the United Nations. This is not a cold-war programme. It is a peace programme."

THE MEDICAL REGISTER

THE Medical Register for 1950 contains 78,140 names of doctors, an increase of 1848 on last year's total and 211 more than the highest number previously recorded (77,929 in 1947). The drop in 1948 was due mainly to the termination of 4467 temporary registrations, mostly foreign. The new registrations in 1949 numbered 3109, which is 859 less than in 1948 (the peak year) but still 56 above the average for the last ten years. The Commonwealth list has increased by 489 to 6570, and the foreign list by 102 to 1905.

The Register is published for the General Medical Council, 44, Hallam Street, London, W.1, by Constable & Co., 10, Orange Street, W.C.1. It is in two volumes and the price is 42*s*.

ACCOMMODATING THE RHEUMATIC

THE British Rheumatic Association is launching a scheme to convert a large block at St. Ann's, Buxton, to accommodate rheumatic patients. The scheme, which is being promoted by B.R.A. Homes Ltd., a housing society with charitable status, calls for the equipment of 60 amenity beds for those who cannot get urgently needed treatment in hospital but who can get it in Buxton as outpatients under the National Health Service Act. In addition, there will be 30 furnished flatlets for elderly disabled rheumatic sufferers needing nursing care. Inclusive charges for beds will range from 2 to 4 guineas and for flats from 4 to 6 guineas. Patients will be received from all parts of the country, but later it is hoped to open similar homes in each of the hospital regions. A total sum of about £50,000 is needed for the present scheme. Donations should be addressed to B.R.A. Homes Ltd., 5, Tite Street, London, S.W.3. Loan stock, bearing interest at 3% per annum, is also to be issued.

DEFINITION OF DRUGS

At the end of 1948 a committee of the Central Health Services Council and the Scottish Health Services Council was set up, under the chairmanship of Sir Henry Cohen, to provide guidance on borderline preparations that might be regarded as either drugs or foods.[1] In its first report[2] the committee lists as foods about 125 preparations, which should therefore not be prescribed free under the National Health Service. These preparations include various baby, milk, invalid, and vitamin foods: glucose preparations: liquid foods, including all alcoholic beverages, wines, tonic wines, and spirits; malt-extract preparations; meat and vegetable extracts and juices; and mineral and spa waters. Certain preparations are regarded by the committee as drugs when used, for example, in the treatment of tuberculosis or vitamin deficiency, but as foods when used as a routine measure for healthy persons such as school-children, factory workers, and athletes. The report, which has no statutory force, is being circulated to practitioners taking part in the service. The committee is to report next on toilet preparations.

University of Oxford

Mr. E. A. Crook has been returned unopposed by the general medical electorate as a member of the board of the Faculty of Medicine.

University of Cambridge

On May 6 the following degrees were conferred:

M.D.—*M. H. Masina, H. H. Wolff, A. B. Bratton.
M.B., B.Chir.—*W. P. Kelly, *I. I. Bornstein.

* By proxy.

On Monday, May 22, at 5 P.M., Dr. A. L. Banks will give his inaugural lecture as professor of human ecology. He is to speak on Man and his Environment.

University of Birmingham

Dr. B. S. B. Wood, senior registrar at the Birmingham Children's Hospital, has been appointed lecturer in pædiatrics and child health.

Mr. D. L. Woodhouse, PH.D., has been appointed lecturer and senior research fellow in chemical pathology, and Dr. A. Lasnitzki senior research fellow in biochemistry. Both these posts are tenable in the cancer research laboratory under Prof. J. W. Orr.

Royal College of Surgeons of England

At a meeting of the council on May 11, with Sir Cecil Wakeley, the president, in the chair, Mr. R. V. Cooke was elected a member of the court of examiners. Dr. David Slome, reader in physiology at the Middlesex Hospital Medical School, was appointed professor of applied physiology in the college. The Cecil Joll prize for 1950 was awarded to Sir Thomas Dunhill for his work on surgery of the thyroid.

Diplomas of membership were granted to the candidates named in the report of the comitia of the Royal College of Physicians which appeared in our issue of May 6 (p. 887).

Dr. Slome, whose appointment to the chair of applied physiology is announced above, will take up his new post on Oct. 1.

Dr. Slome is a graduate of the University of Cape Town. There he took his M.A. in 1926 and his PH.D. in 1929. The following year he graduated M.B. with honours and was awarded the gold medal. Later he gained many scholarships and awards including the Hallett prize. He has been a demonstrator in physiology at St. Bartholomew's Hospital and a lecturer in physiology at the Middlesex Hospital, where he now holds a readership in physiology in the University of London. He has also he[illegible] Mackinnon research scholarships and [illegible] Gale lecture to the college. He is c[illegible] clinic organised by the L.C.C. His published work includes papers on the ætiology of traumatic shock, and on the pituitary and pigmentary effector system.

Order of St. John Investiture

On May 18, at St. Bartholomew's Hospital, Sir Horace Evans received the insignia of commander of the order. Rear-Admiral Lionel Strugnell, Dr. E. W. C. Thomas, Major Phineas Weiner, R.A.M.C., and Dr. T. P. Lalonde received their insignia as officers.

West London Medico-Chirurgical Society

The annual banquet of the society will be held on Friday, June 2, at the Royal College of Surgeons, Lincoln's Inn Fields, W.C.2, at 8 P.M.

Scottish Society of Anæsthetists

This society, whose activities had been suspended since 1939, met at Dunblane on April 29 and 30, under the presidency of Dr. John Gillies. Dr. H. H. Pinkerton was elected vice-president, and Dr. R. N. Sinclair hon. secretary and treasurer.

Society of Public Analysts and other Analytical Chemists

At a meeting of the biological methods group to be held at 2.15 P.M. on Tuesday, May 23, at 11, Chandos Street, London, W.1, there will be a discussion on the assay of vitamin B_{12}. Mr. S. K. Kon, D.SC., will be in the chair.

Claims to Sickness Benefit

In England and Wales new claims to sickness benefit under the National Insurance Act during the weeks ended April 4, 11, 18, and 25 numbered 135,000, 80,700, 127,300, and 121,700. The weekly averages during the twelve months from April, 1949, to March of this year were as follows: 114,400, 97,700, 83,500, 78,600, 88,800, 100,900, 119,100, 136,200, 96,700, 154,900, 178,100, and 181,000.

Irish Medical Schools and Graduates Association

At a dinner held in London on May 3, Mr. J. Johnston Abraham, the president, presented Dr. Ivan Magill with the Arnott medal for his work in anæsthesia. The new president, Sir William MacArthur, was endowed with the chain of office for the coming year. Those wishing to join this association, which was founded in 1878, should write to the secretaries at 149, Harley Street, W.1.

Bone Structure

The recently formed Bone and Tooth Society will hold a symposium on this subject at 5 P.M. on Tuesday, June 6, at the Institute of Orthopædics, 234, Great Portland Street, London, W.1. Prof. W. D. Newcomb will be in the chair, and the other speakers will be Miss Honor Fell, D.SC., Dr. H. A. Sissons, Dr. J. J. Pritchard, Dr. T. F. Dixon, and Dr. H. J. Rogers. Dr. Dixon, who is secretary of the society, may be addressed at the institute.

Health Services in Northern Ireland

In Northern Ireland, which has a population of 1¼ million, the total expenditure during the last financial year on general health services was £3,759,160. The Hospital Authority received £5,400,000. The 716 doctors were paid £1,200,000, the 524 chemists £1,200,000, and 6 million prescriptions were issued, at an average cost during the first six months of 4s. per prescription. The 303 dentists received £1,100,000 and attended 195,000 patients, of whom 76,000 were provided with dentures. The average payment per dentist was £4128, and the highest payment to a single dentist was £8847.

B.M.A.

The British Medical Association is offering next year an occupational health essay prize of £50. This is open to any member of the association who is engaged, either whole-time or part-time, in the practice of occupational health. Candidates may choose their own subjects.

In 1951 the association is also offering prizes to medical students for essays on the Importance of Accurate History-taking in Diagnosis. Further particulars may be had from the secretary of the association, B.M.A. House, Tavistock Square, London, W.C.1.

Chelsea Clinical Society

At this society's annual dinner, on May 9, Dr. Maurice Bewley, the retiring president, replied to the toast of The Society, proposed by Commander Allan Noble, M.P. Commander Noble referred to the value of such societies as this, and went on to suggest that the general practitioner should be afforded more time for real doctoring, for study, and for refreshing himself. The Guests were toasted by Mr. Eric Steeler, and in his reply Sir Charles Harman spoke with humour of his experience of divergent medical opinions in civil actions. Mr. V. B. Green-Armytage uttered a warning that, owing to the National Health Service Act, local medical societies were in danger of extinction. Mr. Geoffrey Parker was inducted as president.

MAIDA VALE HOSPITAL MEDICAL SCHOOL, W.9
5 P.M. Dr. Marion Greaves: *Clinical neurological demonstration.*

Appointments

DYSON, F. L., M.D. Lond., M.R.C.P.: consultant physician, Mi Glamorgan Hospital Management Committee Group.

HESLING, A. G., M.B. Lond., M.R.C.P., D.C.H.: consultant pædi trician to hospitals in Blackpool and Preston Hospital centre

MUMFORD, R. H., M.B. Edin.: appointed factory doctor, Hem worth district, Yorks.

ODDIE, J. A., D.S.C., M.B. Lond.: asst. M.O., East Anglian Region Hospital Board.

OLLERENSHAW, G. J. W., M.A., B.M. Oxfd: *M.O., Gillette Industri Ltd., Isleworth, Middlesex.*

TAYLOR, F. H., O.B.E., M.D. Durh., D.P.H., D.P.M., B.HY.: region psychiatrist, South-West Metropolitan Regional Hospit Board.

Hospital for Sick Children, Great Ormond Street, London:

COX, P. J. N., B.M. Oxfd, M.R.C.P., D.C.H.: house-physicia (junior registrar grade).

COYLE, J. V., M.B., B.SC. Glasg.: house-surgeon (junior registra grade).

D'ARCY, JOAN, M.B. Belf.: asst. medical registrar (registra grade).

JONES, I. C., M.R.C.S.: resident aural registrar (registrar grade).

LAWSON, D. N., M.D. Camb., M.R.C.P.: medical registrar an pathologist (senior registrar grade).

MACAULAY, J. C., M.B. Lond., M.R.C.P., D.C.H.: asst. medica registrar (registrar grade).

South-East Metropolitan Regional Hospital Board:

Consultant Surgeons:

HERIOT, A. J., M.S. Lond., F.R.C.S.: Camberwell group o hospitals.

LILWALL, B. G. A., D.S.O., M.B. Lond., F.R.C.S.: Canterbur and Isle of Thanet group of hospitals.

STANLEY, B. E. C., M.B. Lond., F.R.C.S.: Medway and Grave end group of hospitals.

Consultant Physicians:

EMSLIE, A. G., M.D. Aberd., D.P.H.: Eastbourne group o hospitals.

LIPSCOMB, J. M., M.D. Camb., M.R.C.P.: Canterbury and Isl of Thanet group of hospitals.

PRICE, T. M. L., M.D. Lond., M.R.C.P.: Lewisham and Woolwi group of hospitals.

SOUTHWELL, NEVILLE, M.A., M.D. Camb., M.R.C.P.: Orpingto and Sevenoaks group of hospitals.

Consultant Obstetricians and Gynæcologists:

BURTON-BROWN, JEAN, M.D. Lond., F.R.C.S., M.R.C.O.G.: *Canterbury and Isle of Thanet group of hospitals.*

CHESTER, A. W., M.D. Durh., M.R.C.O.G.: Dartford group o hospitals.

TORRANCE, LYDIA, M.D. Glasg., F.R.C.S., F.R.C.O.G.: Woolwich group of hospitals.

Consultant Orthopædic Surgeons:

BAIRD, R. C., F.R.C.S.E.: South-East Kent and Canterbury group of hospitals.

EPPS, P. G., M.B. Lond., F.R.C.S.: Medway and Gravesend group of hospitals.

Consultant Anæsthetists:

BLAZEBY, R. H., M.R.C.S., D.A.: Canterbury and Isle of Thanet group of hospitals.

FARQUHAR, J. K., M.R.C.S., D.A.: Sidcup and Swanley group of hospitals.

SEARLE, J. B., M.A., B.M. Oxfd, D.A.: South-East Kent group of hospitals.

Births, Marriages, and Deaths

BIRTHS

CAIRNS.—On April 27, at Melbourne, Australia, the wife of Dr. John Cairns—a daughter.

FOX.—On May 6, the wife of Dr. D. L. Fox—a daughter.

LITTLE.—On May 9, at Whitby, the wife of Dr. J. D. Little—a son.

MAITLAND.—On May 11, in Glasgow, the wife of Mr. A. Ian L. Maitland, F.R.C.S.E.—a son.

NEVILLE.—On May 11, in London, to Dr. Alison Neville (née Boodson), wife of Dr. Joseph Neville—a son.

MARRIAGES

MCCORMACK—BRADLEY.—On May 6, at Wisbech, Michael Patrick McCormack, F.R.C.S., to Janet Bradley, S.R.N.

SAVAGE—STUTCHBURY.—On May 9, in London, Paul Thwaites Savage, F.R.C.S., to Anne Stutchbury.

DEATHS

CARTER.—On May 11, at *Enfield*, Ernest Christison Carter, M.D. Edin., M.R.C.P., aged 84.

DAVIDGE.—On May 11, at Sevenoaks, George Sandys Davidge, L.R.C.P.I., surgeon captain, R.N. retd, aged 76.

ELLIOTT.—On May 7, Thomas Robert Elliott, L.R.C.P.I.

FULLERTON.—On May 4, at Pembury, Arthur Hugh Theodore Francis Fullerton, major, R.A.M.C. retd.

HAYWARD.—On May 7, at Walmer, William Davey Hayward, M.B. Manc., aged 81.

HOGG.—On May 7, at Launceston, Tasmania, Gustave Heuzé Hogg, M.D. Edin., aged 81.

MOTHERSOLE.—On May 12, at Bolton, Robert Devereux Mothersole, M.D., M.S. Lond., F.R.C.S., aged 84.

PETERS.—On May 8, at Nailsea, Glos, Benjamin Alfred Peters, B.A., M.D. Camb., D.P.H.

TROTTER.—On May 5, Margaret Jarvey Trotter (née Brown), M.B. Glasg.

USHER.—On May 9, Ruth Dorothy Usher, M.A. Camb., M.R.C.S.

WEATHERHEAD.—On May 8, at Dunbar, Alfred George Norton Weatherhead, M.B. Edin.

WILSON.—On May 9, at Hambleden, Henley-on-Thames, Andrew Steward Wilson, M.B. Aberd., aged 70.

MULTIPLE-LEAD ELECTROCARDIOGRAMS*

IAN G. W. HILL
C.B.E., T.D., M.B. Edin., F.R.C.P.E., F.R.S.E.
LECTURER IN THERAPEUTICS, UNIVERSITY OF EDINBURGH; ASSISTANT PHYSICIAN TO THE ROYAL INFIRMARY, AND PHYSICIAN TO THE DEACONESS HOSPITAL, EDINBURGH

EARLY in my postgraduate days the late Dr. W. T. Ritchie directed my attention to Craib's (1930) studies on the fundamental electrophysiological basis of electrocardiography which cut drastically across the conceptions long taught by physiologists. Soon afterwards I was associated with F. N. Wilson of Ann Arbor, who had independently published similar studies (Wilson et al. 1933a and b) and reached very similar conclusions. These American writers pointed out that the idea that the action current is monophasic derived from records made from muscle strips suspended in air, and they showed that when the currents were led from strips immersed in a conducting medium very different polyphasic curves resulted.

Some knowledge of this electrical background is essential for full understanding of the modern electrocardiogram (E.C.G.). The generally accepted theory of cell polarisation is as follows:

> An inactive or resting cell is electrically polarised, the cell membrane being the boundary or interface between the opposite charges. Activity of the cell—i.e., contraction of a muscle-fibre or excitation of a nerve-fibre—is associated with rapid depolarisation of the cell membrane, the surface of the active tissue becoming electronegative. When the cell passes again to the resting phase, repolarisation takes place in the same order as that in which depolarisation took place.

The original physiological work, done on moist strips of muscle suspended in air, and using bipolar leads, yielded a diphasic type of curve, which was explained as the algebraic summation of two monophasic curves, one derived from each electrode. As proof, the workers crushed or injured part of the strip, thereby preventing its taking part in the excitation process, and led from a point on healthy muscle to a point on the injured zone. A simple monophasic curve resulted.

DOUBLET HYPOTHESIS

Craib however in 1930 showed that, by leading from a single point on a strip immersed in a conducting medium to a distant indifferent point in the medium, a complex polyphasic curve resulted. Similarly, if the partially injured strip in the above experiment was immersed, the curve obtained was no longer simple monophasic. Such curves cannot be explained on the simple negativity hypothesis. It must be remembered that in such experiments we are leading from outside the cells of the tissue strip; the only variable is the amount of fluid bathing the tissue, and this cannot effect the electrical change within the cells, though it modifies profoundly the distribution of potentials in the fluid medium.

By logical argument based on his experimental results Craib showed that the observed phenomena of initial positivity and later negativity of a unipolar electrode on the surface of contacting tissue could be explained on the basis of his "doublet" hypothesis. This implied that the passage of the excitation wave along the fibre was associated with the passage of a series of anodes and cathodes, existing close together and at the same instant at the tissue surface, and arising from a common electromotive force within the tissue. In the transatlantic idiom of Wilson, whose contemporary and independent conclusions were similar, the doublet is replaced by "dipole" and "anode and cathode" by "source and sink." The latter term expresses succinctly the idea that current leaves the fibre at one point (source or anode) and enters at an adjacent sink or cathode.

Direct experimental proof of the existence of such conditions at the surface of a single cell has been furnished in recent years. Using microdissection methods, physiologists in Britain and America (Hodgkin and Huxley 1939, 1945, Cole and Curtis 1939) have introduced fine electrodes into the giant axon of the squid and recorded the potential differences across the cell membrane at rest and during activation. It has been confirmed that the interior of the cell at rest is electronegative, about 40–60 mV below the surface potential. During excitation the action potential swings over to the opposite sign, but proved unexpectedly to be about twice the resting value. Simple depolarisation on the lines of the old membrane theory does not suffice to explain this phenomenon. Hodgkin and Katz (1949) suggest that changes in the relative permeability of the cell membrane to sodium and potassium ions during rest and activity may be responsible for the electrical effect. The height of the action potential in their experiments closely paralleled the concentration of sodium ions in the medium bathing the axon.

I have redrawn Craib's figures with the polarity reversed from the original plates, because the standard physiological technique is to connect the galvanometer so that upward deflection of the string indicates relative negativity of the right arm electrode. This is still clinical practice in recording the standard E.C.G. leads I, II, and III. In leading from the precordium, however, it has become usual to connect the galvanometer so that an upward deflection of the string reflects relative positivity of the electrode on the chest. I fought a losing battle against this method many years ago (Willcox and Lovibond 1937, Hill 1937), and, in accordance with democratic principles, have now conformed to the will of the majority. The curves by this technique certainly resemble ordinary standard-lead E.C.G., but at a cost of complexity of theory that many find perplexing.

Fig. 1 therefore shows Craib's curves redrawn in the new polarity. It will be seen that in the immersed strip the rapid depolarisation, with negativity of the surface electrode is preceded by a definite positive wave, both in leads from simple muscle strips and from the intact frog heart. This positive wave represents the approach of the anode of the doublet, and the swing over

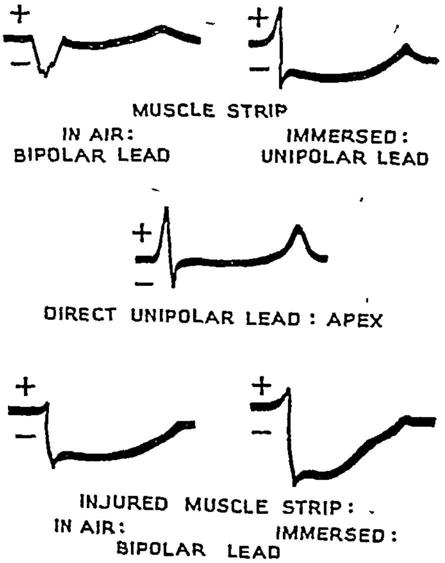

Fig. 1—Bipolar and unipolar leads from muscle strips in air and immersed, and from the intact heart. (After Craib, with polarity reversed.)

* The George Alexander Gibson Lecture delivered before the Royal College of Physicians of Edinburgh on March 25, 1949.

Diary of the Week

MAY 21 TO 27

Monday, 22nd

Royal College of Physicians, Pall Mall East, S.W.1
5 P.M. Prof. E. C. Dodds, F.R.S.: Recent Advances in Endocrinology in relation to Diagnosis and Treatment. (Second lecture.)

Institute of Neurology, National Hospital, Queen Square, W.C.1
5 P.M. Dr. Arne Torkildsen (Oslo): Value of Angiography in the Diagnosis of Intracranial Neoplasms, with special reference to the Cerebral Gliomas.

Newsholme Lecture
6.15 P.M. (London School of Hygiene, Keppel Street, W.C.1.) Sir Henry Cohen: The Clinical Contribution to Public Welfare. (First lecture.)

Tuesday, 23rd

Royal College of Physicians
5 P.M. Dr. J. T. Ingram: Treatment of Eczema.

University of London
5 P.M. (St. Mary's Hospital, W.2.) Prof. Perrin H. Long: Use of Antibiotics in the Treatment of Infectious Diseases with special reference to the Effect of Aureomycin and Chloramphenicol.

Institute of Neurology
5 P.M. Prof. Olof Sjöqvist (Stockholm): Spinothalamic Tractotomy (Anterolateral Chordotomy) with special reference to Late Results.

Institute of Dermatology, Lisle Street, W.C.2
5 P.M. Dr. L. Forman: Abnormalities of the Hair.

Newsholme Lecture
6.15 P.M. Sir Henry Cohen: The Clinical Contribution to Public Welfare. (Second lecture.)

Eugenics Society
5.30 P.M. (Burlington House, Piccadilly, W.1.) Mr. R. C. K. Ensor: Quantity and Quality of the Population of Great Britain.

Wednesday, 24th

Royal College of Surgeons, Lincoln's Inn Fields, W.C.2
3.45 P.M. Dr. Russell Reynolds: Cineradiographic demonstration of Orthopædic Subjects.
5 P.M. Mr. P. H. Mitchiner: Diseased Joints. (Erasmus Wilson demonstration.)

Institute of Psychiatry, Maudsley Hospital, S.E.5
4.30 P.M. Dr. K. Cameron: Lecture-demonstration.

Institute of Neurology
5 P.M. Prof. G. Guillain (Paris): Life and Neurological Work of Pierre Marie.

Institute of Ophthalmology, Judd Street, W.C.1
5.30 P.M. Mr. J. H. Doggart: Diabetes Mellitus and the Eye.

Harveian Society of London
8.15 P.M. (26, Portland Place, W.1.) Dr. W. S. C. Copeman, Dr. J. H. Cyriax, Dr. W. S. Tegner, Dr. Francis Bach: *Problems of Fibrositis.*

Newsholme Lecture
6.15 P.M. Sir Henry Cohen: The Clinical Contribution to Public Welfare. (Last lecture.)

Thursday, 25th

Royal College of Physicians
5 P.M. Dr. A. P. Thomson: Myelomatosis.

Institute of Child Health, Hospital for Sick Children, Great Ormond Street, W.C.1
5 P.M. Dr. Ph. Sandblom (Stockholm): Factors Influencing Growth. (Simpson-Smith lecture.)

Institute of Neurology
5 P.M. Prof. Almeida Lima (Lisbon): Cerebral Angiography—Technique and Generalities.

Institute of Ophthalmology
5.30 P.M. Mr. E. D. D. Davis: Diseases and Affections of the Nose in relation to the Orbit.

Westminster School of Medicine, Horseferry Road, S.W.1
5.30 P.M. (Meyerstein theatre.) Clinicopathological meeting on Erythroblastosis Fœtalis.

St. George's Hospital Medical School, S.W.1
4.30 P.M. Dr. A. Feiling: Neurology lecture-demonstration.

University of Birmingham
5 P.M. (Medical School.) Dr. Frances Braid: Hypothyroidism in Childhood. (First Ingleby lecture.)

Honyman Gillespie Lecture
5 P.M. (University New Buildings, Teviot Place, Edinburgh.) Dr. G. D. Matthew: Tubal Factor in Female Sterility.

Friday, 26th

Royal College of Physicians
5 P.M. Dr. E. N. Allott: The Rhesus Factor.

Institute of Neurology
5 P.M. Professor Lima: Cerebral Angiography—Diagnosis of Tumours of the Cerebral Hemispheres.

Institute of Ophthalmology
5.30 P.M. Mr. A. G. Cross: Retrolental Fibroplasia.

Royal College of Surgeons
5 P.M. Mr. F. S. Gorrill: Anatomy of the Bone. (Arnott demonstration.)

Maida Vale Hospital Medical School, W.9
5 P.M. Dr. Marion Greaves: Clinical neurological demonstration.

Appointments

Dyson, F. L., M.D. Lond., M.R.C.P.: consultant physician, Mid-Glamorgan Hospital Management Committee Group.

MULTIPLE-LEAD ELECTROCARDIOGRAMS*

IAN G. W. HILL
C.B.E., T.D., M.B. Edin., F.R.C.P.E., F.R.S.E.
LECTURER IN THERAPEUTICS, UNIVERSITY OF EDINBURGH;
ASSISTANT PHYSICIAN TO THE ROYAL INFIRMARY, AND
PHYSICIAN TO THE DEACONESS HOSPITAL, EDINBURGH

EARLY in my postgraduate days the late Dr. W. T. Ritchie directed my attention to Craib's (1930) studies on the fundamental electrophysiological basis of electrocardiography which cut drastically across the conceptions long taught by physiologists. Soon afterwards I was associated with F. N. Wilson of Ann Arbor, who had independently published similar studies (Wilson et al. 1933a and b) and reached very similar conclusions. These American writers pointed out that the idea that the action current is monophasic derived from records made from muscle strips suspended in air, and they showed that when the currents were led from strips immersed in a conducting medium very different polyphasic curves resulted.

Some knowledge of this electrical background is essential for full understanding of the modern electrocardiogram (E.C.G.). The generally accepted theory of cell polarisation is as follows:

> An inactive or resting cell is electrically polarised, the cell membrane being the boundary or interface between the opposite charges. Activity of the cell—i.e., contraction of a muscle-fibre or excitation of a nerve-fibre—is associated with rapid depolarisation of the cell membrane, the surface of the active tissue becoming electronegative. When the cell passes again to the resting phase, repolarisation takes place in the same order as that in which depolarisation took place.

The original physiological work, done on moist strips of muscle suspended in air, and using bipolar leads, yielded a diphasic type of curve, which was explained as the algebraic summation of two monophasic curves, one derived from each electrode. As proof, the workers crushed or injured part of the strip, thereby preventing its taking part in the excitation process, and led from a point on healthy muscle to a point on the injured zone. A simple monophasic curve resulted.

DOUBLET HYPOTHESIS

Craib however in 1930 showed that, by leading from a single point on a strip immersed in a conducting medium to a distant indifferent point in the medium, a complex polyphasic curve resulted. Similarly, if the partially injured strip in the above experiment was immersed, the curve obtained was no longer simple monophasic. Such curves cannot be explained on the simple negativity hypothesis. It must be remembered that in such experiments we are leading from outside the cells of the tissue strip; the only variable is the amount of fluid bathing the tissue, and this cannot effect the electrical change within the cells, though it modifies profoundly the distribution of potentials in the fluid medium.

By logical argument based on his experimental results Craib showed that the observed phenomena of initial positivity and later negativity of a unipolar electrode on the surface of contacting tissue could be explained on the basis of his "doublet" hypothesis. This implied that the passage of the excitation wave along the fibre was associated with the passage of a series of anodes and cathodes, existing close together and at the same instant at the tissue surface, and arising from a common electromotive force within the tissue. In the transatlantic idiom of Wilson, whose contemporary and independent conclusions were similar, the doublet is replaced by "dipole" and "anode and cathode" by "source and sink." The latter term expresses succinctly the idea that current leaves the fibre at one point (source or anode) and enters at an adjacent sink or cathode.

Direct experimental proof of the existence of such conditions at the surface of a single cell has been furnished in recent years. Using microdissection methods, physiologists in Britain and America (Hodgkin and Huxley 1939, 1945, Cole and Curtis 1939) have introduced fine electrodes into the giant axon of the squid and recorded the potential differences across the cell membrane at rest and during activation. It has been confirmed that the interior of the cell at rest is electronegative, about 40–60 mV below the surface potential. During excitation the action potential swings over to the opposite sign, but proved unexpectedly to be about twice the resting value. Simple depolarisation on the lines of the old membrane theory does not suffice to explain this phenomenon. Hodgkin and Katz (1949) suggest that changes in the relative permeability of the cell membrane to sodium and potassium ions during rest and activity may be responsible for the electrical effect. The height of the action potential in their experiments closely paralleled the concentration of sodium ions in the medium bathing the axon.

I have redrawn Craib's figures with the polarity reversed from the original plates, because the standard physiological technique is to connect the galvanometer so that upward deflection of the string indicates relative *negativity of the right arm electrode.* This is still clinical practice in recording the standard E.C.G. leads I, II, and III. In leading from the precordium, however, it has become usual to connect the galvanometer so that an upward deflection of the string reflects relative positivity of the electrode on the chest. I fought a losing battle against this method many years ago (Willcox and Lovibond 1937, Hill 1937), and, in accordance with democratic principles, have now conformed to the will of the majority. The curves by this technique certainly resemble ordinary standard-lead E.C.G., but at a cost of complexity of theory that many find perplexing.

Fig. 1 therefore shows Craib's curves redrawn in the new polarity. It will be seen that in the immersed strip the rapid depolarisation, with negativity of the surface electrode is preceded by a definite positive wave, both in leads from simple muscle strips and from the intact frog heart. This positive wave represents the approach of the anode of the doublet, and the swing over

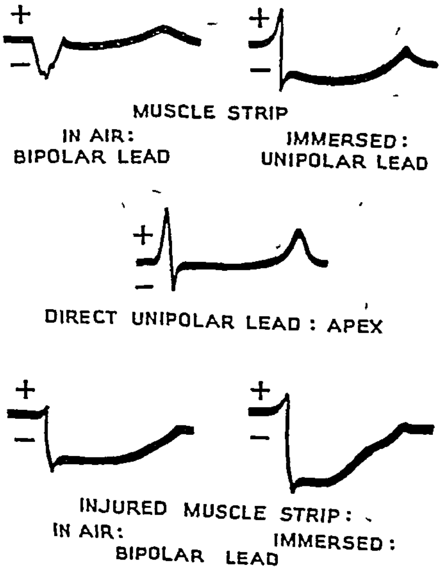

Fig. 1—Bipolar and unipolar leads from muscle strips in air and immersed, and from the intact heart. (After Craib, with polarity reversed.)

---

* The George Alexander Gibson Lecture delivered before the Royal College of Physicians of Edinburgh on March 25, 1949.

to negative signals the passing of the electrode by the interface between resting and activated muscle. A similar positive wave precedes the "monophasic" injury curve from partially crushed muscles, and from the conditions of the experiment can only reflect changes at the electrode on the uninjured tissue.

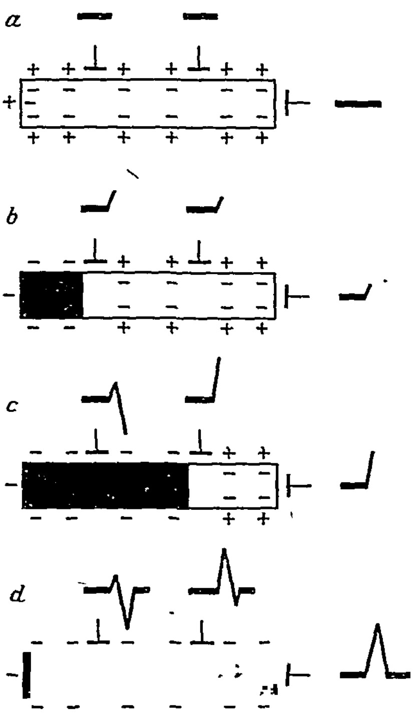

Fig. 2—Schema of genesis of action currents. Unipolar leads from a muscle strip. Black indicates activated muscle.

In fig. 2 the genesis of such curves is illustrated. The excitation wave approaching the electrodes causes relative positivity of each. Its passage beyond the first two electrodes causes a sharp swing over to negativity at each electrode. This very rapid deflection, signalling the arrival of the excitation curve below the electrode, is known as the intrinsic deflection (see below). It will be noted that, at the end of the fibre, excitation causes merely a return of the galvanometer to zero potential, and no deep S wave as at the other electrodes. This is natural, since at the end of the fibre the cathode never passes the electrode, though the anode of the doublet approaches and reaches it. It is indicated in the diagram that the R wave is higher when much muscle is activated before the excitation wave reaches the electrode (see below).

Turning to the ventricular muscle as a whole (fig. 3), we know that excitation normally proceeds centrifugally from the subendocardial Purkinje system toward the epicardium (Lewis 1916). It seems that an electrode on the surface would show similar positive and negative phases, or R and S waves, to those figured from a muscle strip. And Craib's figure (fig. 1) is proof that this is so. It is also apparent that the ventricular cavity is negative from the start, facing the earliest activated part of the muscle. Leads from the cavity of the ventricle in the dog are of the expected type, as was found by many experiments in which I was participant in Wilson's laboratory (Johnston et al. 1935a and b, Wilson et al. 1934a, 1935, 1933).

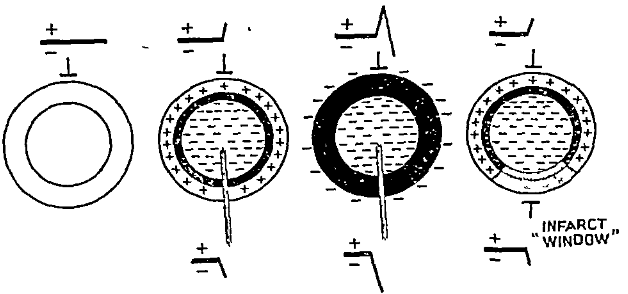

Fig. 3—Schema of surface and cavity leads from ventricle during activation. Black indicates activated muscle. Above, direct lead from surface; below, lead from ventricular cavity.

From these theoretical considerations there emerge three principles, all applicable in the first instance only to the direct leads from the heart wall: (1) the intrinsic deflection in a unipolar lead signals the arrival of the excitation wave below the electrode; (2) the height of R bears some relation to the thickness of the underlying muscle; and (3) leads which show no R and S but are negative from the outset (Q) reflect the potential of the ventricular cavity. Each of these principles has an important bearing on clinical work.

RELATION OF ELECTROGRAMS TO PRECORDIAL E.C.G.

The next point in my argument is to discuss what relation these direct leads (or electrogram) bear to leads from the chest wall overlying the heart (or precordial electrocardiogram). In the work with Wilson cited above we made many experiments on dogs in which curves obtained from the intact chest wall were compared with those obtained directly from the epicardium at corresponding points; a third set of "semi-direct leads" obtained from electrodes separated from the heart by a cotton-wool pad soaked in Ringer's solution or in saline solution were also recorded. The parallelism between the three sets of curves was very close. This was a constant finding. It must not be assumed, however, that a given chest lead in man reflects exactly the changes taking place at an underlying point in the muscle. Nearby areas each add their contributions, less significant as their distance from the focal point increases, distorting the curves to a moderate degree. In general, however, a lead from the chest wall reflects principally the changes in the muscle nearest to it.

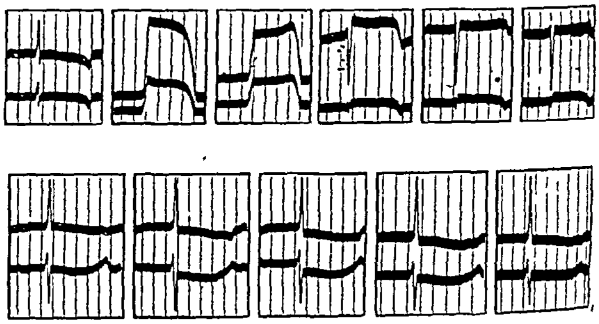

Fig. 4—Electrocardiograms of turtle's heart, showing effects of injury. Above, anterior burn; below, posterior burn. Direct unipolar leads, anterior. Two galvanometers with amplifier in circuit of upper string.

GENESIS OF THE MONOPHASIC CURRENT OF INJURY

Fig. 4 illustrates the changes recorded in direct leads from the front of the turtle heart when areas on the front and the back of the heart are injured by superficial burning. The explanation of the curves may be aided by a diagram (fig. 5*a*), from which it will be seen that, when the resting muscle or cell is injured, the polarisation over the damaged area is lost. This means in effect that the surface in that area becomes electronegative in relation to that of adjacent uninjured muscle. A unipolar lead from such damaged tissue will cause *a constant negative* deflection in the galvanometer, with the result that the string takes up a position below the iso-electric line. By means of the compensator (or equivalent condenser centring device) the string is brought back to zero by introduction of a positive potential in the circuit. When now the uninjured muscle is activated and in turn depolarised, the original potential difference between uninjured and injured muscle is abolished; both are depolarised. The compensating current, now unbalanced, throws the string to a new position above the iso-electric line, which is maintained until the muscle passes again into the resting polarised state. This rectilinear monophasic deflection, lasting throughout systole, is therefore to be expected when leading from over damaged tissue, and is the basis of the so-called monophasic action current of the old school of negativity physiologists. Its importance in practical medicine lies in the fact that its presence betrays the existence of damaged muscle. In experimental work such curves are readily obtained. The period of injury during which such monophasic curves are recorded is short; such is evident in the curves from the turtle heart. In coronary infarction in man they persist longer but are in general transient, lasting only a few hours or days.

This monophasic injury current causing RT or ST shift is the earliest sign of damage to heart muscle in experiment or in clinical practice. The direction of the shift in human myocardial infarction, as in the injured turtle heart, depends on the location of the damaged area; this shift is upwards when the epicardial, and downwards when the endocardial, surface faces the exploring electrode (figs. 5*b* and *c*). The physical basis underlying the observed phenomena had been analysed by Wilson et al. (1934b and c), by Bayley (1942), and Pruitt and Valencia (1948). The occurrence of RT deviation with through-and-through infarction and its persistence in many cases of cardiac aneurysm (Rosenburg and Messinger 1949) present difficult theoretical problems.

The subsidence of ST shifts is closely associated with the development of T-wave changes. In the experimental curves T inversion begins to appear as ST elevation diminishes, and deep inversion of T persists in survival experiments for some days or weeks after the ligation. So in man, the leads showing ST elevation initially show later deep inversion of T, as was described by Parkinson and Bedford (1929). Conversely, in leads with initial ST depression the T waves become high and upright as the ST shift lessens. T waves of very large amplitude are recorded in experiments from the margins of the infarcted area.

QRS CHANGES IN EXPERIMENTAL MYOCARDIAL INFARCTION

We have seen that the ventricular cavity is electronegative from the start of, and throughout, ventricular systole. When an area of muscle is killed, or so damaged temporarily that it does not respond to the excitation wave, the inert damaged muscle contributes nothing to the spreading electrical events except its constant injury current. It conducts passively the potentials of the underlying chamber, and acts, as it were, as a window through which the negative ventricular potential is transmitted to the epicardial surface. A lead from over such an infarcted area therefore shows no R and S waves but simply a Q, similar to that recorded from an insulated copper wire, bare only at its tip, thrust into the ventricular cavity (fig. 3). Records of this type from dog hearts in experimental coronary ligation showed constantly that the potential variations of the cavity and those of the epicardium overlying an infarct were identical (Johnston et al. 1935a and b, Wilson et al. 1934a, 1935, 1933).

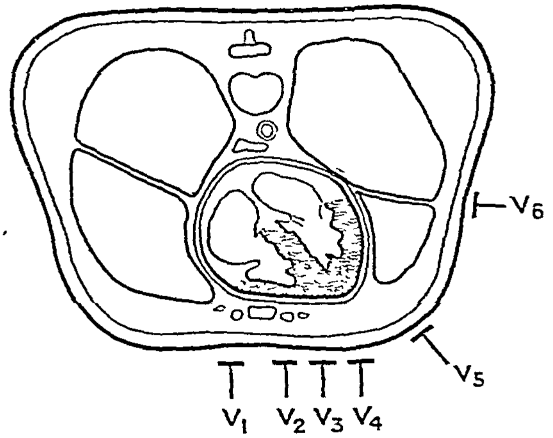

Fig. 6—Transverse section at level of 4th sternocostal junction, to show relation of chest electrodes to heart.

PRECORDIAL LEADS

We have seen how in the dog precordial leads reflect with fair accuracy the potential variations of subjacent points on the epicardial surface. In man precordial leads were introduced by Wilson (Wilson et al. 1926), and much of the early work was done in his laboratory (Wilson et al. 1933c) and by Wood, Wolferth, and their collaborators (Wood, Wolferth et al. 1932, 1933, 1934). These leads came into general use in the last fifteen years, and the interpretation of their results is based on the theoretical considerations just discussed. At first each worker selected a method of leading at his own whim, and within a few years complete confusion had arisen. "Quot homines tot sententiæ"—or, in this case, "so many methods." Individuals chose different points on the chest wall for application of one electrode and placed the other on any one of the four limbs, on the back of the chest, or elsewhere. The old and the new polarity were used indifferently by many, and chaos reigned.

It was at this point, in 1938, that a joint committee of the American Heart Association and the Cardiac Society of Great Britain and Ireland (1938, 1939) sought to standardise the methods of leading: polarity was agreed on, the size and position of the chest electrode defined, and a simple method of labelling leads beyond possibility of confusion devised. On that committee the British members did not agree to adopt the multiple precordial leads which were later standardised by the American members for their own country (American Heart Association 1943). The use of such multiple leads has, however, become

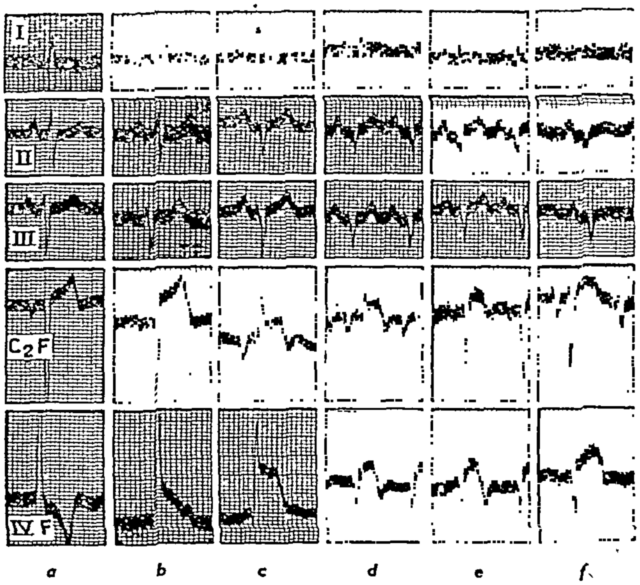

Fig. 7—Serial electrocardiograms in coronary occlusion in a man of 58 (clinical onset 1 p.m., Jan. 29, 1947): *a*, 11.40 a.m. on Jan. 29; *b*, same day, 20 minutes after onset; *c*, same day, 3 hours after *b*; *d*, Jan. 30; *e*, Jan. 31; *f*, Feb. 10.

general in Britain, and a committee of the Cardiac Society of Great Britain and Ireland (1949) has now recommended their official adoption here.

The places selected for applying the chest electrode are numbered serially from right to left of the precordium, and are defined as follows:

1. Right margin of sternum in fourth intercostal space.
2. Left margin of sternum at same level.
3. Midway between 2 and 4.
4. Mid-clavicular line in fifth intercostal space.
5. Left anterior axillary line.
6. Mid-axillary line at same level as 4.

7 and 8. Points at the same level in the posterior axillary line and below the apex of the scapula may be used for additional leads.

The relation of these sites to the heart chambers can be appreciated from fig. 6, which represents a transverse section of the thorax at the level of the fourth costosternal articulations. It will be seen that 1 and 2 are over the right heart, 5 and 6 over the left, and 3 overlies the septal region: 4 may lie over the left ventricle or possibly the septum, according to the size and position of the heart.

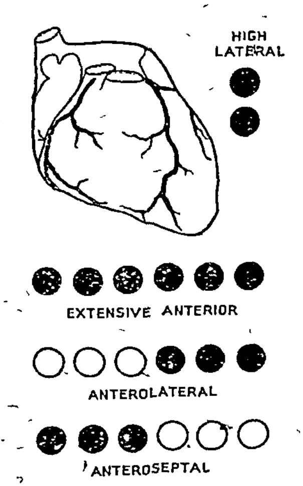

Fig. 8—Varieties of anterior infarcts. Black indicates chest leads showing changes.

So much for the location of the precordial electrode. An electrocardiogram, however, demands two contacts on the body, and the other electrode may be placed theoretically anywhere. Since the body is a volume conductor, the potential variations at the heart are transmitted to all parts of the body, the magnitude of the potentials decreasing as the distance from the heart increases (Wilson 1930, 1943, Wilson et al. 1933a and b). If one electrode is applied over the precordium, and the other to an extremity, the resultant curve is the algebraic sum of the potential variations at the two points of application. These variations are much larger at the precordial electrode than at the peripheral; hence the curves reflect fairly accurately the changes underlying the precordial electrode. The curves may be labelled CF, CR, or CL according as the second electrode is on the left leg, right arm, or left arm.

Wilson et al. (1934e), recognising that the potentials of the extremity, though relatively small, introduced an error into the tracings, considered as precordial curves, introduced the technique of unipolar leads. On theoretical grounds and by experiment he showed that, if

the three limbs (right arm, left arm and left leg) are connected to a central common terminal through resistances of 5000 ohms or more, the central point does not vary appreciably in potential throughout the cardiac cycle. The theory was attacked from many quarters, and experimental evidence was adduced against it. Eventually, however, the theory and practice were abundantly vindicated, and the method of leading from the precordium to such a "null point" is now widely accepted and has been recommended by the Cardiac Society of Great Britain and Ireland (1949). Such leads are "unipolar" since, for practical purposes, they reflect the potential variations of only one electrode, that on the precordium. To distinguish them briefly from other chest leads, they are known as V leads (voltage leads). Such V leads may be recorded from any part of the body —e.g., from the limbs—hence the potential variations of, say, the right arm, left arm, and left leg can be recorded. These leads are known as VR, VL, and VF respectively, while the precordial are labelled V_1, V_2, V_3, &c., in sequence from right to left. It is clear that the standard lead I, from right arm to left arm, with the usual (physiological) polarity, is the algebraic sum of − VR and + VL, since polarity is reversed in the accepted chest-lead technique. So lead II is − VR + VF, and lead III is − VL + VF.

Modifications have been introduced by Goldberger (1942, 1947); the first dispenses with the resistances mentioned above, thus making for technical simplicity in recording; the second causes augmentation of the limb unipolar leads without significant change in their form. Limb leads by this technique are labelled for brevity *a*VR, *a*VL, and *a*VF; these labels are used throughout the clinical section of this paper.

In Britain today various centres follow different systems of leading. In some, precordial leads are taken with the right arm as the "indifferent" electrode, yielding CR leads; for over ten years most of our curves in Edinburgh Royal Infirmary were taken with the left leg as the indifferent point (CF leads). In several hospitals, however, the unipolar (V) leads have been adopted, and these are now current practice in this laboratory. Before discarding the CR and CF systems, however, one should consider their relation to, and possible advantages over, the unipolar leads. A great objection is that curves obtained by such leads are compounded of two independent variables, one admittedly small, but none the less affecting the curve in a way unpredictable unless the potential variations of the distant electrode are known. Unipolar leads are "pure" without distortion from the distant electrode. In favour of the CR leads Evans (1949) states that by this method an inverted T is never found in certain leads in health, whereas by V leads T inversion in V_1 and V_2 may occur in normal people. This seems a specious premise on which to base a preference, and one which has caused no trouble in interpretation. An important argument in favour of V leads is that their adoption facilitates the recording of unipolar limb leads, which in certain conditions yield information of the highest value in the interpretation of E.C.G. (see below). The papers by Bain and Redfern (1948), Letham (1949), Cameron (1949), and Wood (1949) should be consulted for details of the problem.

In summary, an E.C.G. today in most laboratories includes some 12 leads: the 3 standard leads, the 3 unipolar limb leads, and 6 unipolar precordial leads. Fewer precordial leads suffice in some cases; additional leads are required in others.

E.C.G. CHANGES IN MYOCARDIAL INFARCTION

Armed with our knowledge of the changes produced by injury to the heart muscle in direct leads, let us consider the clinical E.C.G. of infarction in man. The case from which these records (fig. 7) were made has already been reported (Branwood 1947). I was implicated solely in the interpretation of the E.C.G.

A man, aged 58, who was subject to effort angina and had had duodenal ulcer, had a routine E.C.G. taken at 11.40 A.M. on Jan. 29, 1947. Twenty minutes later he sustained a clinical

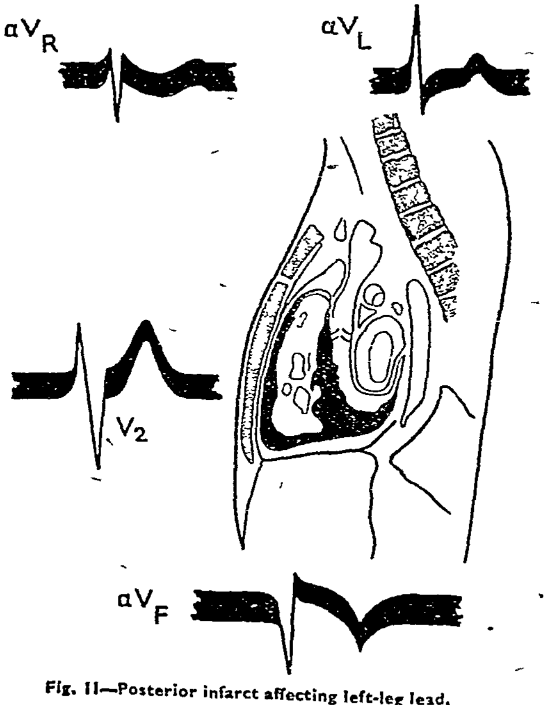

Fig. 11—Posterior infarct affecting left-leg lead.

x 2

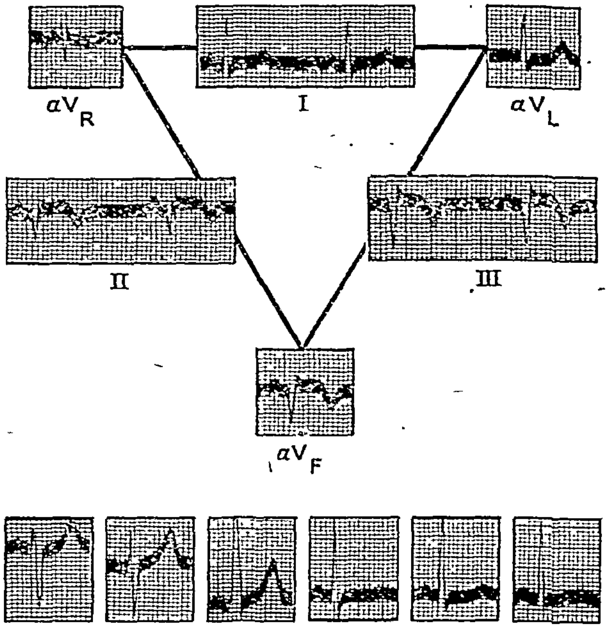

Fig. 12—Electrocardiograms in case of "posterior" infarction.

perforation of a peptic ulcer, and an hour thereafter, at 1 P.M., developed precordial pain suggesting a superadded coronary infarction. A record at 1.20 P.M. already shows ST changes in the two recorded chest leads. The development of ST shifts, Q R S changes, and later T inversions can be followed in fig. 7. From the ST elevation in figure *c* it is apparent that the epicardial surface of injured muscle faces the apical electrode. In *d*, *e*, and *f* the tell-tale Q waves are obvious, indicating that the surface electrode over the apex looks through inactive (dead) muscle into the ventricular cavity; T inversion had begun to appear in the lead showing ST elevation before death supervened. The double diagnosis was confirmed by necropsy, death having taken place on the fourteenth day after the onset of acute symptoms. The sequence of E.C.G. changes is noteworthy.

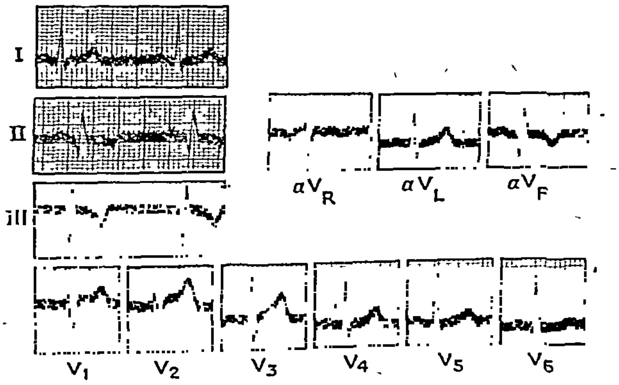

Fig. 13*a*.

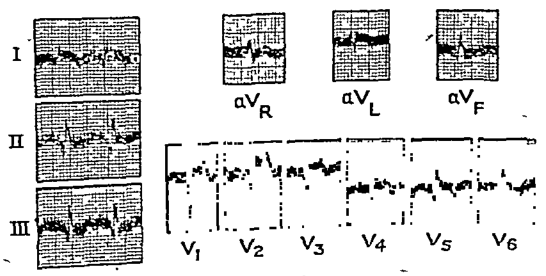

Fig. 13*b*.

We might predict that the E.C.G. changes in precordial leads, so far as Q R S deformity is concerned, would be confined to cases of infarction of the anterior surface, and that the particular leads affected would depend on the exact location of the infarct. Thus, extensive infarction will show changes in all or most of the six leads (fig. 8), whereas anteroseptal and anterolateral infarcts will affect only the leads from points overlying the lesion. The three common types of anterior infarct are illustrated by clinical curves in fig. 9.

Infarcts of the upper part of the left lateral wall (Wilson et al. 1946) may only show changes in special leads from higher interspaces. In such high lateral infarction deep Q waves are visible in leads from over the affected area, and smaller Q waves persist in all higher spaces right up to the left shoulder, with the result that the left-arm unipolar lead may show tell-tale changes when the standard leads are equivocal and the usual chest leads silent (fig. 10).

In a large proportion of infarcts the "posterior" surface of the heart is involved, from occlusion of the circumflex branch of the left, or part of the right, coronary artery. Anatomically this surface is not truly posterior but inferior or diaphragmatic; the posterior aspect of the heart is occupied by the left auricle (fig. 11). In infarction of this surface the precordial leads show no Q R S changes, though downward ST shifts appear in recent cases. But the left-leg unipolar lead, though distant, looks directly at the infarcted surface and might be expected to show Q R S changes similar to those in precordial leads in anterior infarction. The curves in this figure have been redrawn from an actual case of posterior infarction and show the relationship expected.

In lead *a*VF the Q wave of the "infarcted window" is obvious; there is ST elevation, since the lead faces the epicardial aspect of the injured area, and T inversion as usual develops later where ST elevation was found in the early stages. In the full set of leads (fig. 12) from this patient it is apparent that only lead *a*VF and those derived from it (standard leads II and III) show the infarct pattern. It is therefore understandable how so-called posterior infarcts are more readily diagnosed

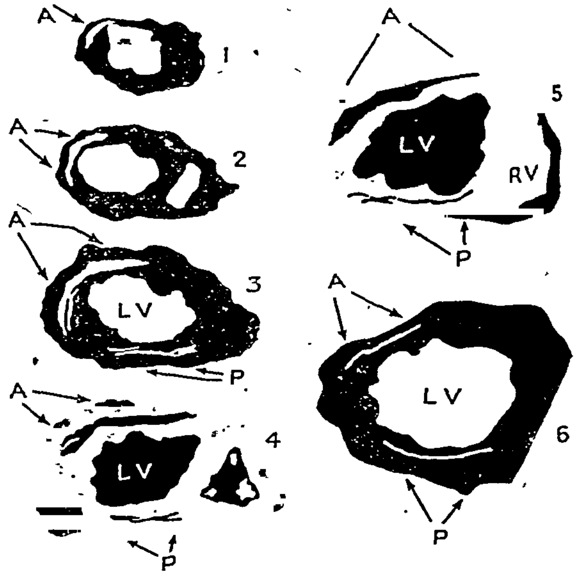

Fig. 13*c*.

Fig. 13—Male, aged 54, first attack of clinical coronary infarction on June 25, 1947; second attack on Dec. 25, 1948; death in congestive failure on Jan. 2, 1949: *a*, electrocardiograms 1 year after first infarction; *b*, electrocardiograms 6 hours after second infarction; *c*, drawings of heart serial sections 1 cm. thick from apex to base, position of old posterior (P) and new anterior (A) infarctions being indicated in white.

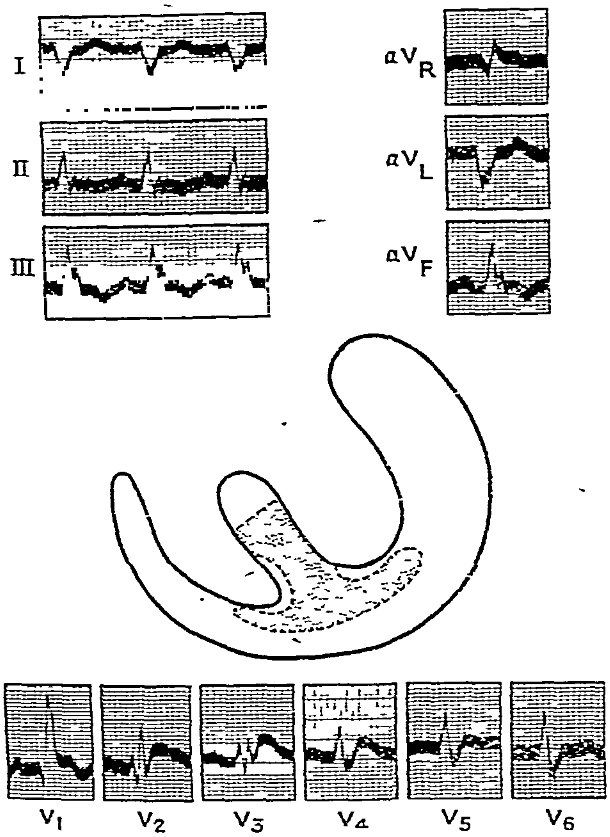

Fig. 14—Electrocardiograms from a case of septal infarction.

from standard lead curves than from precordial leads. In modern practice lead *a*VF is recorded, since a prominent slurred Q in that lead is strongly in favour of infarction, even if changes in the standard leads are minimal. Records made with the exploring electrode in the œsophagus (Brown 1936, Hamilton and Nyboer 1938, Myers and Klein 1948) may yield curves in posterior infarction comparable to those of precordial leads in anterior lesions. They are, however, unsuitable for use in ill patients.

An example, confirmed by necropsy, of the E.C.G. diagnosis of infarction is shown in figs. 13*a*. *b*, and *c*).

A man, aged 54, sustained an attack of clinical coronary thrombosis on June 25, 1947. The E.C.G. 23 days later indicated a posterior lesion, and records a year later were still characteristic and unchanged. On the morning of Dec. 25, 1948, he had a second attack, and the E.C.G. on the same day indicated a fresh anterior infarction. Despite admission to hospital and treatment with heparin, the patient developed auricular fibrillation and congestive heart-failure and died suddenly on the ninth day of illness. At necropsy both infarcts, old posterior and fresh anterior, were found in the predicted locations.

The interventricular septum is involved to a greater or less extent in many infarcts. On occasion gross infarction of the septum occurs which may produce puzzling E.C.G. changes.

For example, the rare type of right bundle branch block was associated with ST deformities and small Q waves (fig. 14) in a patient who had clinically had a very recent infarction preceded by another several days before. At necropsy gross septal infarction, with less extensive infarction of the anterior and posterior walls, was found.

These isolated examples of post-mortem correlation of pathological findings and E.C.G. diagnosis illustrate the close correspondence that is shown in such large series as those of Myers et al. (1948, 1948b, 1949). Space forbids further detailed discussion of the E.C.G. changes produced by infarction, but brief mention must be made of one or two important points. First, the E.C.G. diagnosis rests most surely on progressive changes when such can be demonstrated in serial records, and this is particularly applicable to cases in which the curves do not conform to the classical types. Secondly, E.C.G. changes may be delayed in their appearance, and serious difficulty may arise if diagnosis is attempted from a single early tracing. This should be borne in mind especially perhaps in cases in which the diagnosis lies between a surgical abdominal emergency and a coronary infarction. Thirdly, the QRS changes described above are those of massive transmural infarction. Where the whole thickness of the muscle is not involved, R waves and intrinsic deflections may persist from the outset, or reappear early after initial suppression, and ST and T changes alone are evident.

Lastly, some other conditions may mimic the E.C.G. pattern of myocardial infarction, in particular the state of acute cor pulmonale following massive pulmonary embolism (McGinn and White 1935, Murnaghan et al. 1943). The combination of deep S waves in lead I and of Q and inverted T waves in lead III, together with T inversion in the leads from the right precordium, all relatively fleeting, indicate pulmonary rather than coronary infarction. Right bundle-branch block commonly occurs as an early transient phenomenon (Durant et al. 1939). Characteristic E.C.G. changes occur also in some cases of pericarditis (Bellet and McMillan 1938). These are marked by ST elevation in all three standard leads and in the precordial leads. The ST shifts differ from those of infarction in being "concordant" and not opposite in sign in leads I and III. The changes are not present in all cases. I recently had under my care a case of terminal pericarditis complicating uræmia in which none of the 12 leads recorded showed ST deformity, and at necropsy the whole heart was involved.

(*To be concluded*)

ACHALASIA OF THE PYLORUS IN ADULTS

A. F. WILLIAMS
M.B., B.Sc. Manc., F.R.C.S.
CHIEF ASSISTANT, PROFESSORIAL SURGICAL UNIT,
MANCHESTER ROYAL INFIRMARY

PYLORIC stenosis with delay in emptying the stomach is usually due to organic obstruction at the pylorus. When this is caused by congenital hypertrophy of the pyloric sphincter, symptoms usually develop in the early weeks of life, though for many years they may not be particularly obvious. In adults, however, the commoner cause of obstruction is an acquired disease, such as duodenal ulcer.

Some diseases produce a temporary pyloric stenosis or pylorospasm. The lesions may then be in the stomach or the duodenum—e.g., peptic ulceration—or in more distant organs, such as the gall-bladder and the appendix. But cases are seen in which there has been gross retention of gastric contents for many years and yet at operation or at necropsy no lesion can be found in the stomach or the duodenum, and the pylorus appears normal: there is no associated disease which would produce pylorospasm, nor is it reasonable to suppose that such protracted dysfunction of the pyloric sphincter could be merely the result of disease in another organ. This type of lesion was first mentioned by Cruveilhier in 1852 (cited by Lerche 1914). Since this date a few other cases have been noted, and three more are described here.

CASE-RECORDS

Case 1.—A woman, aged 45, had been able to eat anything until seven years before admission to hospital, since when she had had pain and vomited after meals. At first she had vomited small quantities frequently, but in the past year large quantities occasionally, even vomiting food taken a week previously. She had lost 28 lb. in weight.

On examination there was visible peristalsis but no palpable mass in the abdomen. Twenty-four hours after a barium meal radiography showed that practically no barium had left the stomach; the stomach was greatly dilated but no other lesion was seen. A fractional test-meal showed that the acidity was within normal limits, but the curve was of a climbing type.

Operation.—The stomach was grossly enlarged and its wall hypertrophied; the duodenum appeared healthy; and neither organ showed evidence of active or healed ulceration. The pylorus seemed perfectly normal. A partial gastrectomy of the anterior Polya type was performed. To the naked eye no stenosis was visible in the pylorus. The pathologist found gastritis and some hypertrophy of the gastric mucosa but no other abnormality. There was no old or recent ulcer.

Progress.—The patient made a good recovery and has had no trouble in the fifteen months since operation.

Case 2.—A woman, aged 62, had for many years had pain an hour after meals. The pain was relieved by vomiting, and there had been remissions. The patient had become worse in the previous year and lost weight.

On admission she had absolute constipation and visible peristalsis, with waves passing up and down, and her abdomen was much distended, particularly on the left side.

Operation.—Intestinal obstruction due to a carcinoma of the colon was suspected; so after appropriate preoperative treatment a laparotomy was performed. All that was found, however, was great enlargement of the stomach with an apparently normal pylorus. An anterior Polya gastrectomy was done. To the naked eye no ulceration or pyloric stenosis was visible. On section the mucosa was œdematous, but there was apparently no lesion of the submucosa or the muscular layers.

Progress.—In the two years since operation the patient has been free from pain and vomiting, but has had anorexia and lassitude and has not gained weight.

Case 3.—A woman, aged 34, had been assaulted and had her nose broken six years ago. A month later she had begun to vomit, at first only in the evening. A few months before admission vomiting had become more frequent, after most meals, and had been copious at times.

On admission in June, 1947, the patient had epigastric tenderness, achlorhydria, and microcytic anæmia. The plasma-chloride level was 550 mg. per 100 ml. and the blood-urea 150 mg.

Progress.—She improved under medical treatment, and in July radiography of the stomach showed no abnormality. After an inflammation in her lungs the vomiting increased and her condition deteriorated, the plasma-chlorides falling to 445 mg. per 100 ml. Administration of saline again effected an improvement, and at this time visible peristalsis was observed and an organic pyloric stenosis diagnosed.

Operation.—On laparotomy the stomach was proved to be moderately distended, the pylorus and duodenum being normal. A posterior gastro-enterostomy was performed, and gross submucous œdema of the stomach was found. Both kidneys were very large and smooth.

Postoperative Progress.—The patient made good progress for two days but then gradually became worse and died nine days after operation, having had epileptic fits and widespread purpura.

Necropsy Findings.—There was slight puckering of the mucosa at one part of the pylorus, with a superficial scar, but no indication which one would expect from a healed or healing ulcer of the usual type. On microscopy the pyloric musculature appeared normal.

DISCUSSION

Ætiology

A considerable number of cases have been described in which pyloric stenosis in adults has been due to congenital hypertrophy, probably of a mild degree, thereby escaping treatment in infancy but permitting the child to reach adult life. In the present cases the most striking feature was the absence of any pyloric abnormality and of a muscular tumour in particular. There is still disagreement about the cause of congenital hypertrophic pyloric stenosis, but one theory is that there is a congenital achalasia of the pylorus which leads to hypertrophy of the prepyloric muscle, which appears as the tumour. If this condition goes untreated the whole stomach becomes hypertrophied, with the result that a localised prepyloric tumour is not found (Netto 1940). In the type of case under discussion symptoms do not arise until adult life, and so a congenital cause for them is most improbable.

Another explanation of the obstruction is that of Maylard (1904, 1920), who considered that the pylorus was concentrically narrower than normal and therefore the reduplication of mucosa there was greater than usual. This explanation, however, was given only after examination of the pylorus at laparotomy and was not based on its laboratory examination.

Russell (1908) described three of these cases, in two of which he thought the pylorus was fibrosed, probably congenitally, for the symptoms were of long standing. Walton (1923) is sceptical about the presence of pyloric stenosis in the absence of organic obstruction, and does not believe that spasm alone can give rise to enough mechanical obstruction to cause characteristic symptoms. He holds that in cases of this nature the primary lesion is visceroptosis, leading to pyloric obstruction by kinking. If, however, there is hypertrophy of the pylorus, he believes it is an old congenital lesion—a view held by most observers. He also attributes the so-called simple fibrosis of the pylorus to visceroptosis, because it does not improve after gastro-enterostomy; but he has not personally seen such a condition not associated with ulceration.

Hurst (1925) recognised that pylorospasm could be secondary to other lesions, especially peptic ulceration, but he also described a case in which at laparatomy no lesion of the pylorus could be found and no corrective operation done.

Severe obstruction occurs at other levels of the alimentary tract without any apparent change in the sphincter concerned, notably at the cardiac and pelvi-rectal sphincters. It is now generally believed that in these cases the underlying trouble is an imbalance between the components of the autonomic nervous system—either an underaction of the parasympathetic or an overaction of the sympathetic.

It would be surprising if a similar abnormality did not occur at that most important sphincter, the pylorus. The present three cases and some of those previously reported should be regarded as due to achalasia of the pylorus. Considerable weight is afforded to this argument by the fact that in some of the published cases achalasia of the cardiac sphincter was present as well as the pyloric stenosis, suggesting that the two lesions were similar in nature.

The 19 cases described by Maylard (1904, 1908), 2 by Russell (1908), 1 by Hurst (1925), and 3 by Netto (1940) can probably all be included in this category. It is unlikely that the lesion is congenital, since in the great majority of the cases symptoms do not begin until adult life; and few clinicians would now accept visceroptosis as a cause of severe pyloric obstruction. A possibility which must be considered is a prolapse of gastric mucosa, but in the cases described here there was no evidence of this. The symptoms from prolapsed mucosa are extremely variable, but pain is the most prominent, with vomiting relatively rare, and in none of the recorded cases has there been the extreme dilatation of the stomach noted here. The radiological appearances may be mistaken for those of a duodenal ulcer, but some abnormality is generally observed. At operation the prolapse is usually easily palpable, or laxity of the mucosa may be recognised in the specimen (Scott 1946, Manning and Highsmith 1948).

That a muscle tumour or fibrosis of the pylorus was not the underlying cause was excluded by macroscopical and microscopical examination of the specimens. In all, when examined microscopically, there was an entire absence of any fibrous tissue in excess of normal.

It is rather more difficult to decide whether the muscle of the pylorus is within normal limits, because its thickness varies with the age, weight, and height of the individual, and considerable variations may occur as the result of fixation. However, in all three cases neither the surgeon nor the pathologist regarded the pyloric muscle as hypertrophied on naked-eye examination, and the localised tumour which occurs in infants was absent. When the specimens were sectioned and examined microscopically the muscle again appeared to be within normal limits. They have all been examined by Dr. E. R. A. Cooper, who also regards the size of the pylorus as within normal limits.

An almost identical picture may be produced after vagotomy, a fact which lends strong support to the argument that the condition is due to autonomic imbalance, and suggests that it may be due to loss of vagal function from some unknown cause. Whatever may be the reason for the achalasia, it seems to be acquired during adult life and is presumably more closely related to cardiospasm, which usually arises in adult life, than to congenital megacolon.

In case 3 the onset of symptoms was closely related to a shock, which helps to relate the lesion to a nervous cause.

Clinical Features

A striking feature of this type of case has been the great preponderance of females, almost 5 to 1, in most of whom symptoms began in early adult life. This sex-incidence is quite unlike that in hypertrophic pyloric stenosis and should be sufficient to classify the present type of pyloric achalasia as a separate entity.

Diagnosis should not be impossible, for the patients generally have gross gastric retention—e.g., in case 1 scarcely any barium had left the stomach in twenty-four hours. The symptoms last long but usually do not resemble those due to an ulcer, and the onset in adult life will distinguish the condition from congenital lesions. Pain is not so great as in a patient with an ulcer and is generally relieved by vomiting. Radiography of the stomach and duodenum is of great value in excluding obstruction due to ulceration or to neoplasm and prolapse of gastric mucosa.

Treatment

In the published cases treatment has been usually either gastro-enterostomy or partial gastrectomy. Those described by Maylard (1904, 1908) were all treated by gastro-enterostomy, and after an immediately satisfactory response the original symptoms came back. Of the two survivors described here the response to partial gastrectomy in one has not been very satisfactory, though vomiting has been abolished; and, though the other patient has done well for fifteen months, this is too short a period for proper assessment of the treatment. If the cause is an autonomic imbalance, it is not surprising that the operations have not been very successful. This lack of improvement sometimes follows gastro-enterostomy done to relieve the gastric stasis which may develop after vagotomy.

In the present state of our knowledge the treatment seems to be surgical, and some short-circuit of the pylorus should be made, possibly with excision of the pylorus. If this fails to bring about sufficient improvement, one may consider the possibility of an attack on the sympathetic nervous system—e.g., resection of the splanchnic nerves.

SUMMARY

Three cases of pyloric obstruction without any apparent cause are described.

It is considered that the obstruction in these and similar cases is due to achalasia of the pylorus.

The clinical picture and treatment are discussed briefly.

I wish to thank Prof. A. M. Boyd for his advice, Prof. John Morley for his criticism, and Dr. E. R. A. Cooper for examining the microscopical sections.

UTILISATION OF HIGH-FAT DIET AT LOW TEMPERATURES

A. R. C. BUTSON
A.M., M.A., M.B. Camb.
LATE MEDICAL OFFICER, FALKLAND ISLANDS DEPENDENCIES SURVEY: HONORARY RESEARCH ASSISTANT, UNIVERSITY COLLEGE, LONDON

IT is generally accepted that man's tolerance to a high-fat diet is greatly enhanced by living in a cold climate. For the polar traveller such a diet has been accepted as the most efficient, because fat will give more calories per unit of weight than any other food. When, however, the fat content of the diet exceeds a certain limit, fat metabolism cannot be completed and ketone bodies accumulate in the blood and are excreted in the urine. Ketonæmia gives rise to serious, even fatal, symptoms. Shafier (1921) developed a trial method of calculating the ketogenic/antiketogenic (K/AK) ratio of the elements of the diet from gramme-molecular weights of the components in various foodstuffs: if the K/AK ratio does not exceed 1, ketonæmia will not occur. Woodyatt (1921) developed a similar empirical formula for the fatty acid/glucose ratio, which should never exceed 1·5.

Probably, however, the limiting factor to ingestion of a high-fat diet is the lack of palatability. It is well established that fat has a specific inhibitory effect, through the hormone enterogastrone (Ivy et al. 1935), on the secretion of gastric juice and on the movements of the stomach.

Recently attention has been focused on the problems of (1) man's tolerance to a high-fat diet (Consolazio and Forbes 1946) and (2) tolerance to cold as affected by the diet (Mitchell et al. 1946). Consolazio and Forbes investigated the effects of a high-fat diet, composed of pemmican, with a 50% fat composition, in a temperate environment, and found that only one out of eight men could tolerate such a diet, and that this man developed ketonuria. Mitchell *et al.* found that men's tolerance to cold (exposure to −20°F for four hours) was superior on a high-fat diet, composed 55% by weight of fat, than on a high-carbohydrate or high-protein diet of the same caloric value.

Hawley et al. (1933) pointed out that tolerance to a high-fat diet, in the sense of better oxidation of fat, could be acquired. Heinbecker (1928), in studies on Eskimo metabolism, demonstrated the capacity of the Baffin Land and Polar Eskimo to excrete remarkably

I wish to thank Mr. R. J. Rutherford for permission to report this case, and Mr. D. B. Smith, supervisor of the laboratory of the department of surgery, Edinburgh, for the photograph.

UNSUCCESSFUL TREATMENT OF ASCARIASIS WITH HETRAZAN

M. J. Colbourne
M.B. Edin.
MEDICAL OFFICER, COLONIAL MEDICAL SERVICE

'Hetrazan' (1-diethylcarbamyl-4 methylpiperazine hydrochloride) has been used by Oliver-Gonzalez et al. (1949) in the treatment of six patients infested with *Ascaris lumbricoides*. All worms were apparently removed from three of the patients, and in the other three the egg-count was considerably reduced.

Confirmation of these results was sought in the treatment of patients admitted to hospital at Winneba, Gold Coast.

Material and Method.—The stools of all patients admitted were examined microscopically; concentration methods were not used. The intensity of the infection was estimated by the number of ova of *A. lumbricoides* per coverslip preparation.

Alternate patients with ascariasis were treated with hetrazan, the other patients with ascariasis being treated with oil of chenopodium, the routine treatment at Winneba. Those treated with hetrazan were thirteen females and eleven males, aged 6–65 years, with an average of 50 ova per coverslip preparation. Those treated with oil of chenopodium were eleven females and thirteen males, aged 5–62 years, with an average of 41 ova per coverslip preparation.

Dosage.—The dosage of hetrazan was that recommended by Oliver-Gonzalez et al.: 2 mg. per kg. of body-weight eight-hourly for twenty-four hours. Eight hours later a saline purge was given.

Treatment with oil of chenopodium was as follows. Twenty-four-hours' starvation was followed by a saline purge in the evening. At 6 A.M. next day adults were given oil of chenopodium 1 ml. in a solution of sodium sulphate; two hours later another saline purge was given. The dose of oil of chenopodium was reduced proportionately for children.

Results.—Stools were examined for worms during the next three days; on the morning of the third day after treatment the number of ova per coverslip preparation were counted. The findings were as follows:

	Oil of chenopodium	*Hetrazan*
No. of cases	24	24
Ascaris found in stools after treatment	15	7
Stool findings on 3rd day:		
Stools cleared of ova	19	11
No. of ova per coverslip preparation reduced by more than 50%	5	7
No. of ova per coverslip preparation reduced by less than 50%	—	6

Two patients treated with hetrazan without reduction in the number of ova per coverslip preparation were treated with oil of chenopodium a week later. Both passed worms, and in both cases the number of ova in the stool was reduced. No toxic effects of treatment were observed either with hetrazan or with oil of chenopodium.

Most of the worms passed by both groups of patients were alive.

SUMMARY

Twenty-four patients infested with *Ascaris lumbricoides* were treated with hetrazan, and twenty-four with oil of chenopodium.

In the dosage used hetrazan was less effective than oil of chenopodium in the treatment of ascariasis.

I wish to thank Dr. R. L. Cheverton, director of medical services, Gold Coast, for permission to publish this note.

RHEUMATIC AORTIC ANEURYSM IN A BOY OF 19

K. Dorry Loutfy
M.B. Cairo, M.R.C.P.
ASSISTANT PROFESSOR OF MEDICINE, FAROUK UNIVERSITY, ALEXANDRIA

Aortic aneurysm is rare in young people. In 184 cases reported by Cowan and Ritchie (1935) the youngest patient was aged 29 and 14 were under the age of 39. It is uncommon to find in the more recent published reports patients under the age of 30, but in the older reports aneurysms were described in young people; possibly their disappearance is due to improved methods of treating syphilis. Le Boutillier (1903) reviewed 80 cases of aneurysm, of which 23 were aortic, in patients under the age of 20. Of these 80 patients 13 were under 12 years old and the youngest was a child of 2 years, congenital syphilis being the cause of these cases in children. Willson and Marcy (1907) reported a large aortic aneurysm in a child aged 4 years.

Though syphilis is the commonest cause, Bernert (1910) collected 14 reported cases in which aneurysms were associated with rheumatism. In rheumatic aortitis Pappenheimer and Von Glahn (1924) reported numerous scars in the media, but the lesions were much smaller than in syphilitic aortitis. A few years ago, in the Kasr-el-Aini Hospital, Cairo, a case of rheumatic aneurysm of the aorta was confirmed at necropsy. Smallpox, influenza, typhoid fever, and pneumonia have occasionally been accused of weakening the adventitia (Boyd 1940).

In view of the rarity of rheumatic aneurysms the following case is reported.

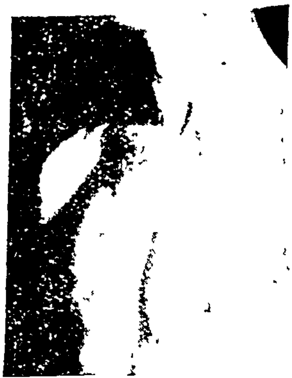

Fig. 1—Anterior surface of chest showing swelling in second right interspace close to sternum.

A boy, aged 19, single, working in an electrician's shop, complained of palpitation, pains in the joints, shortness of breath on exertion, and dry cough for four years. More recently there had been a sense of oppression at night, specially felt behind the sternum. The attacks of rheumatic pain had recurred almost yearly, lasting for three months with fever and swelling of the joints and confining the patient to bed. In the last five years he had had repeated sore throat. Four years ago he had had an attack of severe breathlessness on exertion which lasted three or four hours and was followed by a stitch-like precordial pain with palpitation. The breathlessness had increased, becoming more severe on exertion and worse in the winter. For a month before admission to hospital he had had a dry cough associated with the dyspnœa, and nocturnal dyspnœa had broken his sleep and been accompanied by throbbing headache and retrosternal oppression. Four days before admission he had had fleeting pains in the large joints. There was no history of syphilis in either the patient or his parents. Seven years previously he had had urinary bilharziasis.

On examination he was a normally grown youth of good nutrition. His cheeks were flushed, but his temperature was normal. Capillary pulsation was visible in the skin; in the neck gross pulsations of the carotid arteries were present, together with pulsation in the suprasternal notch. The trachea was central, and a tug could be felt. The pulse was of the water-hammer type, with blood-pressure 140/50 mm. Hg in both arms, and 190/60 in the thigh, where a characteristic Duroziez murmur was audible. There were no signs of peripheral venous congestion. There was a visible pulsating swelling in the second and third right intercostal spaces, just outside the sternum (fig. 1). The apex-beat was in the fifth space 1 in. outside the mid-clavicular line and gave a heaving impulse. In the aortic area there were palpable systolic and diastolic thrills, and thrills with similar timing could also be felt at the mitral area. Systolic and diastolic murmurs were audible in the aortic area, and in the mitral area a harsh systolic murmur was propagated to the axilla, and, following an "opening snap," there was a slightly rumbling mid-diastolic murmur of lower pitch than that heard in the aortic area.

Fig. 2.

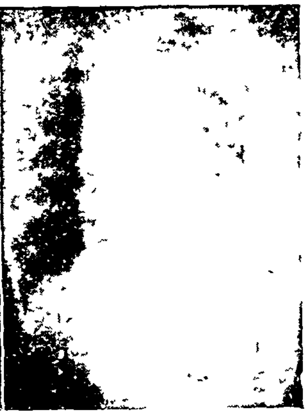

Fig. 3.

Fig. 2—Anterior view of chest, showing enlargement of left side of heart, with diffuse enlargement of whole aortic arch.

Fig. 3—Right anterior oblique view of chest, showing œsophagus indented by enlarged aortic arch.

Investigations.—The Wassermann reaction was negative even after provocative neoarsphenamine. The cerebrospinal fluid was normal, with negative Wassermann. The erythrocyte-sedimentation rate was 8 mm. in 1 hour, and 25 mm. in two hours (Westergren). Blood-culture was negative. Red-cell count 3,680,000 per c.mm.; Hb 70%, white-cell count 9000 per c.mm. (eosinophils 6%). Stools contained ova of ascaris (this condition was treated). Urine contained a trace of albumin; specific gravity 1·030. Radiography of the chest showed diffuse enlargement of the aorta, particularly of the arch (figs. 2 and 3); enlarged left ventricle and auricle; greatest transverse diameter of the heart $17^1/_2$ cm.; transverse diameter of the chest 26 cm. Electrocardiogram showed left ventricular hypertrophy with inverted T wave in all three leads; the P wave was within maximum normal limits.

DISCUSSION

The major features of this case of aortic aneurysm are the youth of the patient and the presence of severe rheumatic heart-disease. There was no clinical or serological evidence of syphilis, and infective endocarditis seems to be ruled out. The rheumatic history was strong, and the murmurs at the mitral area were compatible with a rheumatic lesion of the mitral valve, accompanying rheumatic aortic incompetence. There was no suggestion of dilatation above a coarctation of the aorta, and it is difficult to assign the aneurysm to any cause other than rheumatism.

PITUITOUS CATARRH

J. V. GORDON
M.D. Adelaide, M.R.A.C.P.
RESIDENT MEDICAL OFFICER, REPATRIATION GENERAL HOSPITAL, SPRINGBANK, SOUTH AUSTRALIA

ENUMERATING the various types of bronchitis, Laennec (1823) described a condition which he called idiopathic pituitous catarrh. He said: "I give this name to that variety of catarrh in which the expectoration is colourless, transparent, ropy, frothy on the surface, and underneath like the white of egg diluted with water." He described two varieties: an acute type which may occur at intervals and a chronic form which is often characterised by considerable regularity of the paroxysms of cough and expectoration.

In view of the paucity of published cases this condition seems to be very rare. Reference to it as a special variety of bronchitis is seldom made in standard textbooks, though Davidson (1941) mentions it.

The clinical picture is striking: the patient is subject to extremely severe bouts of coughing, during which he expectorates a large volume of sputum having the characteristics described by Laennec. As much as three pints in twenty-four hours may be produced. Apart from the distressing chest symptoms of cough, sputum, and dyspnœa, the patient's general condition remains good and does not exhibit any evidence of toxæmia such as may be found in chronic thoracic sepsis. The ætiology of the condition is unknown.

The case reported below has been kept under my own observation for a little over two years and has been the subject of numerous investigations.

CASE-RECORD

A carpenter, aged 36, was admitted to hospital on May 6, 1947, with cough, expectoration, and dyspnœa. He said his symptoms had begun in June, 1942, during a training course in jungle warfare in New Zealand. Previously well, he had become ill with severe cough and dyspnœa; he was thought to have bronchopneumonia, and was in hospital for about six weeks. His symptoms improved but little, and from then until the present admission he had continuous chest symptoms which were so severe that he could not do any sustained physical work.

The outstanding feature of his illness was that each night since its onset (five years ago) he was woken by a paroxysm of coughing lasting about $^1/_2$–$^3/_4$ hour, during which he coughed up 1–$1^1/_2$ pints of sputum. As a rule the coughing bout occurred about seven hours after he had fallen asleep (if he went to sleep at 11 P.M. the attack would occur at about 6 A.M.; if he went to sleep at 9 P.M., it would occur at 4 A.M.). After the attack, which was associated with much dyspnœa, he would feel very exhausted and go to sleep again. During the daytime he had little cough and expectorated practically nothing. He always felt exceedingly short of breath, even when resting. Only occasionally did he note any blood in the sputum, and then it was but a mere streak.

He had no other symptoms; his appetite was good, and he had not lost weight. At different times chronic bronchitis, asthma, and bronchiectasis had been diagnosed. Treatment with adrenaline, ephedrine, postural drainage, &c., had been tried without benefit. The patient had been advised to live in a warmer climate and had tried this without any benefit.

Past and family history were uneventful. There was no history of exposure to irritants of the respiratory tract, or of any disease of the upper respiratory tract, and nothing to suggest allergy.

On examination the patient was a well-nourished man weighing 13 st. 10 lb., a little dyspnœic while resting in bed. He was not cyanosed or feverish. His pulse-rate was 75 per min., pulse regular. His cardiovascular system appeared normal; blood-pressure 115/80 mm. Hg. Examination of the lungs revealed no impairment of the percussion note, voice sounds, or breath sounds, but numerous coarse low-pitched rhonchi were heard scattered over both lung fields; there was no evidence of bronchospasm. There was no clubbing of the fingers, and all other systems appeared normal.

I wish to thank Mr. R. J. Rutherford for permission to report this case, and Mr. D. B. Smith, supervisor of the laboratory of the department of surgery, Edinburgh, for the photograph.

UNSUCCESSFUL TREATMENT OF ASCARIASIS WITH HETRAZAN

M. J. Colbourne
M.B. Edin.
MEDICAL OFFICER, COLONIAL MEDICAL SERVICE

'Hetrazan' (1-diethylcarbamyl-4 methylpiperazine hydrochloride) has been used by Oliver-Gonzalez et al. (1949) in the treatment of six patients infested with *Ascaris lumbricoides*. All worms were apparently removed from three of the patients, and in the other three the egg-count was considerably reduced.

Confirmation of these results was sought in the treatment of patients admitted to hospital at Winneba, Gold Coast.

Material and Method.—The stools of all patients admitted were examined microscopically; concentration methods were not used. The intensity of the infection was estimated by the number of ova of *A. lumbricoides* per coverslip preparation.

Alternate patients with ascariasis were treated with hetrazan, the other patients with ascariasis being treated with oil of chenopodium, the routine treatment at Winneba. Those treated with hetrazan were thirteen females and eleven males, aged 6–65 years, with an average of 50 ova per coverslip preparation. Those treated with oil of chenopodium were eleven females and thirteen males, aged 5–62 years, with an average of 41 ova per coverslip preparation.

Dosage.—The dosage of hetrazan was that recommended by Oliver-Gonzalez et al.: 2 mg. per kg. of body-weight eight-hourly for twenty-four hours. Eight hours later a saline purge was given.

Treatment with oil of chenopodium was as follows. Twenty-four hours' starvation was followed by a saline purge in the evening. At 6 A.M. next day adults were given oil of chenopodium 1 ml. in a solution of sodium sulphate; two hours later another saline purge was given. The dose of oil of chenopodium was reduced proportionately for children.

Results.—Stools were examined for worms during the next three days; on the morning of the third day after treatment the number of ova per coverslip preparation were counted. The findings were as follows:

	Oil of chenopodium	*Hetrazan*
No. of cases	24	24
Ascaris found in stools after treatment	15	7
Stool findings on 3rd day:		
Stools cleared of ova	19	11
No. of ova per coverslip preparation reduced by more than 50%	5	7
No. of ova per coverslip preparation reduced by less than 50%	—	6

Two patients treated with hetrazan without reduction in the number of ova per coverslip preparation were treated with oil of chenopodium a week later. Both passed worms, and in both cases the number of ova in the stool was reduced. No toxic effects of treatment were observed either with hetrazan or with oil of chenopodium.

Most of the worms passed by both groups of patients were alive.

SUMMARY

Twenty-four patients infested with *Ascaris lumb* were treated with hetrazan, and twenty-four with oil of chenopodium.

In the dosage used hetrazan was less effective than oil of chenopodium in the treatment of ascariasis.

I wish to thank Dr. R. L. Cheverton, director of medical services, Gold Coast, for permission to publish this note.

Reviews of Books

The Biology of Mental Defect

LIONEL S. PENROSE, M.A., M.D. With a preface by Prof. J. B. S. HALDANE, F.R.S. London: Sidgwick & Jackson. 1949. Pp. 285. 21*s*.

IF the reader approaches this book with the idea that it will provide him with simple and authoritative statements on all the problems which arise in the ætiological aspects of mental deficiency, he will be disappointed. This is not the design of the author. Almost as many questions are asked as are answered, and no attempt is made to conceal by dogmatic generalisations the numerous gaps in our knowledge.

Professor Penrose attacks his subject in an entirely fresh way. He begins with a historical introduction in which more attention is paid to evolution in ideas than in institutions. The result is most readable and stimulating. From this he goes on to the incidence of mental deficiency and the measurement of intelligence, and discusses the relation between intelligence and various physical, social, cultural, and economic factors. After chapters on the problems of classification and causation, there is a valuable section on methods of analysis of statistical data, which should prove of great use to all workers in this field for reference purposes. It is only after this comprehensive introduction that the author enters on the special field of genetics. Chapters on the relation of mental defect to mental disorder and on treatment conclude the work. There is a bibliography of about 500 references, as well as a number of appendices and an index.

Professor Penrose's work should prove invaluable for the research-worker, and as it is full of stimulating ideas anyone with an interest in biology would find many of the chapters fascinating. Professor Haldane in his preface says that he believes that the study of mental deficiency is of considerable philosophical importance; and Professor Penrose does not burke the wider implications of this theme. The answer that is given to the eugenic problem is very cautious. There are probably few among the informed who believe that society should use semi-compulsive eugenic measures on any large scale in the attempt to rid itself of morbid conditions dependent on hereditary factors. The social problem of providing support and care for the idiot and the imbecile is not a major one; and from the racial point of view their occurrence is a matter of no importance. Voluntary sterilisation can be humanely desirable in a limited number of picked families, but it is of little significance to society as a whole. Professor Penrose, however, also has strong objections to positive eugenics—i.e., the encouragement of vigorous and successful people to produce rather more than their fair quota of children. His arguments on this point seem far less strong, but one of them should be allowed great weight in its proper field of application. The vigour of a race and its adaptability to changing circumstances lies very largely in its genetical variability. Any processes which, like the stockbreeding of animals, encourage some desirable qualities at the expense of increasing uniformity must be regarded as dangerous.

The Sulphonamides

F. HAWKING, M.D., National Institute for Medical Research, Mill Hill, London; J. STEWART LAURENCE, M.D., M.R.C.P., physician in charge of the Walkden Clinic, Manchester. London: H. K. Lewis. 1950. Pp. 390. 42*s*.

As the authors of this admirable book state in their preface, the time has now come when a reasonably full and detached account can be given of the sulphonamide drugs. Such a review can also be more or less definitive; for, though the sulphonamides have advanced a long way since the first reports of their activity, it is not now probable that many new properties of this group of drugs will come to light. The authors turned a delay in publication to good account by adding recent Continental views; and this has greatly enhanced the value of the book to the English-speaking reader. The account of the toxic effects of the sulphonamides is especially full, but every important aspect of the drugs has been dealt with adequately and the bibliography is comprehensive. The completed work is something with which to be well pleased. Handsomely produced, and well printed and illustrated, its binding will please eye and hand during the years to come when it will be indispensable to many of us.

Ecology of Health

The New York Academy of Medicine Institute on Public Health, 1947. Editor: E. H. L. CORWIN, PH.D. New York: Commonwealth Fund. London: Oxford University Press. 1949. Pp. 196. 20*s*.

THE words "ecology of health" conjure up a picture of ecological studies on the grand scale. This book represents the quintessence of papers and discussions held as part of the centennial celebration of the New York Academy of Medicine, and the introduction claims that it may be regarded as a point of departure for the next century's progress in public health. For the American citizen this promise may be fulfilled, though it is oddly disappointing to the non-American.

The first chapter is devoted to Genetics and the Public Health, and despite an almost overwhelming preoccupation with the genetic effects of atomic energy and the atom bomb it contains much valuable information. The teaching of genetics to medical students in the United States is examined in detail, and this section should be read by all those planning medical curricula for the future. The reader may be startled to find the recommendation that "it should be mandatory for a man to abstain from acts of reproduction for some two months after his testes have been exposed to any considerable dose of radiation." Next follows a chapter on maternal health and nutrition which gives a clear idea of recent research in the United States and Canada but not elsewhere: war-time experience in Great Britain is not mentioned. The discussion on animal and insect vectors of disease is truly ecological and vividly describes the recent advances in control of epidemic diseases, particularly plague and yellow fever. The chapter on Climate, Geography, and Disease is also world-wide in outlook, though the comment that diphtheria was not at all prevalent in England a hundred years ago is open to challenge. The description of Mills's views on the effects of external heat and the date of conception is interesting. He has found inter alia that of the 32 American Presidents

Investigations.—A blood-count showed red cells 5,200,000 per c.mm., Hb 14 g. per 100 ml. (102%), white cells 6500 per c.cm. (differential count normal). The Wassermann reaction was negative. A Mantoux test (1 in 1000) was positive. Electrocardiography showed a normal tracing. The vital capacity was 3·5 litres. Radiography of the chest showed a little general increase of the lung markings only. A bronchogram revealed no abnormality of the bronchi.

Sputum.—The amount expectorated was 15–25 oz. daily, all of which was produced in $^1/_2$–$^3/_4$ hour. The sputum was neither fetid nor purulent. Laennec's original description fitted it perfectly; the surface of the sputum was frothy, but the bulk of it looked like clear mucus, resembling the "white of egg diluted with water." It could be poured very easily from one sputum mug into another, "flopping" in and leaving the sputum mug clear. No "casts" were found. Microscopically it was acellular. Culture on several occasions revealed only a few contaminants and an absence of any [illegible]sms or fungi. Attempts to isolate a virus [illegible] the sputum was non-albuminous but contained mucin.

Bronchoscopy showed that the mucosa of the bronchial tree appeared a little redder and softer than normal; excessive glairy secretion was coming from all bronchial orifices. The configuration of the bronchial tree appeared normal. A biopsy specimen of the bronchial mucosa showed that the epithelium was tall columnar; its cells show great secretory activity; the submucosa was œdematous and infiltrated with chronic inflammatory cells, particularly in the subepithelial layer and to a lesser extent round the mucous glands; and the mucous glands showed considerable secretory activity.

Subsequent Course.—The patient has been carefully followed for the succeeding two years. His clinical condition has remained unchanged. The nocturnal bouts have been recurring daily with clockwork regularity and without any apparent relation to external environment. Bronchial antispasmodics and anti-histamine drugs have had no effect. Chemotherapy with penicillin, &c., has been useless. Large doses of atropine given to the point of intolerance were tried and, though they diminished the total quantity of sputum, it became more viscid and tenacious, and the patient experienced much distress in attempting to expectorate it. Deep X-ray therapy to the chest was also tried without benefit. Repeated bronchoscopy has revealed little or no change in the appearance of the bronchial mucosa. Successive radiograms likewise have shown no alteration. The quantity and quality of the sputum have not altered in any way. Despite the chronicity of his symptoms the patient's general condition remains good.

DISCUSSION

The diagnosis of this case was at first in doubt. The chronicity of the patient's symptoms, together with their peculiar characteristics, did not conform to any well-recognised disease. Thorough investigation of the chest, including bronchography and microscopical section of the mucosa, did not give much positive assistance. The outstanding feature of the case is that for seven years without remission the patient has coughed up a large amount of sputum each night after going to sleep. The sputum contained no pus and showed merely a large amount of clear mucus-like material. The biopsy report suggested that the secretory glands of the bronchi were extremely active in the absence of any obvious inflammation.

The condition has resisted all forms of therapy, including those directed against possible allergy or infection.

The conclusion appears inescapable that this is an example of *catarrhe pituiteux idiopathique* originally described by Laennec. Probably some of the cases reported by Laennec under this heading may have been confused with cases of bronchial asthma, or cardiac asthma with pulmonary œdema. However, Laennec, mentions several examples which conform to the syndrome encountered in the present patient, and cites one such patient who had "expectorated during the last ten or twelve years, in two daily paroxysms, about four pounds of a colourless, ropy, and frothy fluid."

Hartley and Davies (1923) reported the case of a woman, aged 34, who had a series of acute attacks, especially at night; the average daily amount of sputum was 20 oz., and a 6 oz. container would be filled in 15 minutes. They described the sputum as being "thick, ropy, and homogeneous" and consisting of "mucus looking just like unboiled white of egg," and stated that the other characteristic feature of the sputum was "the ease with which it could be emptied from vessel to vessel, the whole flopping out en masse, leaving the sputum pot clean, save for a little froth near the rim." They commented on the rarity of the condition and suggested that it might be due to excessive secretory activity of the mucous glands of the bronchial tract.

In a case cited by Seyfarth (1932) that came to necropsy, tuberculous bronchial lymph-glands were found, among which the vagus nerve was embedded on one side, and the bronchorrhœa was attributed to vagal irritation; it is difficult, however, to explain the generalised bronchial disturbance on the basis of such a unilateral lesion.

The rarity of pituitous catarrh may be more apparent than real. Possibly some cases are masquerading under a clinical diagnosis of bronchiectasis without radiological proof; others have been merely called chronic bronchitis or asthma despite the lack of any associated sepsis or bronchospasm.

The ætiology is obscure. Pituitous catarrh seems to be unrelated to infective, allergic, or psychic factors. The characteristic clinical picture results from intense hypersecretion of the bronchial glands in the absence of any demonstrable cause, and tends to be paroxysmal and come on especially at night.

I wish to thank Dr. A. B. Anderson, medical superintendent of the Repatriation General Hospital, Springbank, South Australia, for permission to publish this case.

COOMBS TEST IN ACUTE ACQUIRED HÆMOLYTIC ANÆMIA

EARLE HACKETT
M.D. Dubl.
MEDICAL DIRECTOR, NATIONAL BLOOD TRANSFUSION ASSOCIATION, DUBLIN

IN 1946, Boorman et al. reported that the red cells of patients with acute acquired hæmolytic anæmia gave a positive direct Coombs test. This has been confirmed by various workers. On the whole, red cells from these patients are agglutinated rather less avidly in the Coombs test than are red cells sensitised in vitro by specific immune Rh or other antibodies.

In a cross-absorption experiment two samples of the same batch of rabbit anti-human serum (Coombs serum) were respectively absorbed with an equal volume of washed packed cells which were (*a*) from a typical case of severe acquired hæmolytic anæmia and (*b*) normal group-O D-positive sensitised in vitro with an incomplete anti-D antibody. Next, back titrations were done and compared with the titres shown by this particular immune rabbit serum against the cells before absorption (see table).

The untreated rabbit serum was active at a higher titre with the cells sensitised in vitro, and absorption was more complete with these cells; but it can be seen from the back titration that the same component was evidently absorbed from the rabbit serum by both types of sensitised cells. I conclude that, whatever antibody element

Training For General Practice

DR. COLLINGS, in his report, said more than once that nobody had ever satisfactorily defined the scope of general practice. We all thought we knew what it was, or should be; we were willing to comment on its present defects, or suggest improvements for its future; but we did this without accurately delineating its proper sphere. He asked that "an attempt should be made to define the future province and function of general practice within the framework of the National Health Service,"[1] and it is good to see that an attempt of this kind is made in the British Medical Association committee's new report on *The Training of the General Practitioner* (see p. 1008). Before considering recommendations on training, the committee, with Sir HENRY COHEN as chairman, set itself to describe the nature of general practice. An early chapter of the report, after giving accounts of days in the lives of practitioners in different types of practice, goes on to analyse the tasks that general practitioners now perform and must continue to perform. This analysis leads to a chapter comparing and contrasting the work of the general practitioner and the specialist, from which the conclusion is drawn that "general practice, as the continuous medical care of the individual, provides the underlying unity of Medicine, and has as its goal the study of 'the whole man.'"

> "Ultimately, it is in the return of its results to general practice that the fragmentation of Medicine into specialties finds its fullest justification."
>
> "The adequate pursuit of many specialties requires no higher ability, industry, zeal and personality than general practice; indeed some require less."
>
> "... the traditional distinction in status and prestige between general practice on the one hand and any and every specialty on the other is wrong."
>
> General practice "is different in kind from other departments of medicine and the general practitioner must have personal qualities rather different from those of specialists."

It is on the basis of these conclusions, and on the premise that general practice is a calling with special skills of its own, worthy of ranking, when these skills have been acquired, on an equality with other more specialised branches of medicine, that the report proceeds Given this premise, it is natural to ascertain what are the special skills required, and what are the disciplines that will best fit the student to become a worthy practitioner.

The committee rightly insists that up to the time of qualification, and in the pre-registration year that will now follow qualification, there should be no distinction between the education of the future general practitioner and that of the potential specialist. Each should be given the same background of scientific training, based (the committee would prefer) on the principles outlined in the earlier B.M.A. report, *The Training of a Doctor*. Only when he has completed this basic training will the young doctor be ready to make his choice of general practice as a career and to take advantage of the opportunities he should be given for further training. The committee believes that this further training will ordinarily take three more years: the first year should be spent as a trainee under the tutelage of an approved established practitioner; in the second, the future practitioner should go back to a hospital to study hospital practice, with the new perspective acquired from his year in practice; and the third year should be occupied in special studies of the doctor's own choice to meet his particular needs for more knowledge of subjects that especially interest or have previously escaped him. Somewhere, too, in these postgraduate years, service in the Armed Forces will have to be fitted in; and for the present it is proposed that 18 months in uniform should count as 12 months' training, though the year spent in actual general practice must not be shortened. Altogether it is a long extra spell of training that is suggested, and obviously the doctor will have to be adequately paid while engaged in it.

In these days of growing concern, when the content of general practice is changing, and its prestige and attractiveness are falling, it is salutary to have such revolutionary recommendations presented; and they deserve the most careful consideration in the universities and in Whitehall. Opinions will differ as to their practicability, partly because of the prolongation of the already long years of medical training but partly also because of the difficulty of finding enough places in hospitals or in practices where the young graduate would receive proper tuition, encouragement, and experience. Already we are committed to finding internships for a year for the whole student population, while all those proceeding to specialist training must spend some five further years in posts of rising seniority as registrars: can we in addition, find room to give further hospital instruction, for a year or more, to our apprentice G.P.s? Where, too, do we find our trainers among the practitioners? The report is against discrimination, and would have us allow any practitioner of over five years' standing to apply to train a newcomer; but this seems to be too liberal a policy. The apprentices ought surely to be taken under the wing of practitioners who are themselves giving a high standard of service, and who are not so overworked as to have no time to give proper instruction, or so harassed that they may be tempted to unload too big a share of their burden on the inexperienced shoulders of the trainee. Certainly some of the practitioners met by COLLINGS will be unsuitable instructors until they have been enabled to change their manner of practice. The aim is not to teach the young to adapt themselves to the hurried methods of industrial practice, but rather to show them such better ways of organising their working lives that if they eventually undertake such work they will rebel against its present conditions and build something better. Some selection of trainers is in any case inevitable because at any one time there will hardly be more than one trainee, in his apprentice year, for every twenty doctors established in practice

---

11 were conceived in the first quarter of the year, 10 in the second, 7 in the fourth, and 4 in the third.[1] The Atlas of Diseases projected by the American Geographical Society of New York will be a valuable addition to our medical libraries.

A chapter is devoted to realities in preventive psychiatry, and some of the statistics given are surprising. It has been estimated that approximately 8 million people in the United States have now, or have had in the past, some form of mental disease or personality disorder. Of 15 million men examined for military service during the war a total of 2,480,000 were rejected because of neuropsychiatric disorders. This chapter is full of common sense and nobody will dispute the conclusion that "psychiatry today is in the curious position of having acquired, through a tremendous popularisation, a somewhat magical aura while it is still suffering from a carry-over of the medieval attitudes which placed an everlasting stigma on the psychiatric patient." The chapters on trends in State and Local Health Services, the Hospital Survey and Construction Act, and the preparation of professional workers, are of interest mainly to those concerned with future developments within the United States. Lastly there is a glorious finale by Prof. Franklin Bobbit on the education of laymen in health responsibilities in which he attacks the present-day education of adolescents in the United States. After describing the impressive and inspiring custodial institutions, spacious and dignified with ivy-covered walls and cap-and-gown atmosphere, he concludes that "in reality this is education without purpose, since the programs do not aim at the shaping or improvement of any definite human functions."

Though much of this book is devoted to preventive medicine, it contains information of value to all who are interested in the preservation and improvement of the health of mankind. The European reader must be warned not to allow himself to be prejudiced by the predominantly all-American approach.

The Inner Experience of a Psychoanalyst

THEODOR REIK. London: Allen & Unwin. 1949. Pp. 514. 21*s.*

IT is a recurrent charge against psychiatry that it attracts psychopathic practitioners as well as psychopathic patients; there are still medical men who prefer to see themselves as the competent mechanic with the servicing-schedule, dealing with the breakdown and the psychical accident from behind a level surface of common sense and sanity. Dr. Reik is a pupil of Freud who has been in analytical practice too long to accept such a view. Psychiatry involves the interplay of two minds, not a surgical operation by one mind on another. This is not the only field of medicine where introspection, a sense of experience shared with the patient, and even a personal experience of suffering are assets precious to the physician. Dr. Reik returns to the part which Freud's awareness of his own inner conflicts played in providing the driving force behind his study of mental processes. His book looks resolutely towards the personality of the analyst rather than that of his patient. In so far as Dr. Reik's personality emerges, it is a scholarly, sympathetic, and wise one. It is given, perhaps, to a process of thought which releases an idea and follows it by association, looking for experimental evidence to justify, rather than to guide, the course it takes; but such an approach is probably better suited to the business of tracking the strange and the irrational associations in other minds than rigid objective logic. Much of the wisdom is in the humour of the writing, a quality usually lacking in psycho-analytical literature. The chapter on "Psychoanalese" deserves special recommendation to the inexperienced and the amateur Freudian. As Reik says, this is a book for the young worker. In its way, and subject to the limitations of the strict analytical method, it does for its subject something of what the great humanists of medicine have done for general practice. Some of it will be condemned as whimsical; but whimsicality itself can be a point of contact with the surprising behaviour of the deranged mind. This particular psycho-analyst will, the reader feels, be far less congenial to fanatics of his own system than to its critics. He quotes with relish Freud's own remark "Moi, je ne suis pas Freudiste." The technique he advocates depends almost wholly on the personality of the technician. In Dr. Reik's hands it must inevitably be of value, even where it is vague or mistaken.

Maladies du squelette

LUCIEN LEGER, R. DUCROQUET, HENRY LEGER. Paris: Masson. 1949. Pp. 253. Fr. 1200.

THIS well-illustrated and well-written book gives detailed descriptions of the rarer diseases of bone. The authors have compiled largely from previous authors, but their own cases are surprisingly numerous, and carefully described. Albright's disease, bone xanthoma, eosinophil granulomas, and skeletal associations of neurofibromatosis are all covered, and the authors suggest that some common ætiological factor may prevail, or that they may be diverse manifestations of a common pathological process. The curious distribution of lesions is the chief point they establish for this hypothesis; but even if the suggestion is flimsy, the argument is illustrated by elaborate records. Melorheostosis, strain fractures, and so-called essential osteolysis are fully recorded, and a final chapter on myelomata of bone completes a catalogue of rarities. Obviously the authors have considerable experience of the conditions they describe and their book, though it makes rather difficult reading, is a valuable work of reference.

Differential Diagnosis of Chest Diseases

J. J. SINGER, M.D., F.A.C.P., F.C.C.P., medical director, Rose Lambert Foundation, Beverly Hills. London: Henry Kimpton. 1949. Pp. 344. 52*s.* 6*d.*

THIS book, whose title on the outside cover is simply *Chest Diseases*, is a highly condensed account of the subject in which the emphasis has been placed upon the differential diagnosis. A large field is covered, and affections of the diaphragm and thoracic cage are included. Its main defect rests upon the fact that the author has not confined himself to his "terms of reference" but has been beguiled from diagnosis into the realm of treatment. This is particularly apparent in the chapter devoted to the surgical treatment of pulmonary tuberculosis. It is unfortunate that a potentially good book should thus have fallen between two stools, for it contains a great deal of valuable information about the relation between the clinical study of the patient and the help derived from laboratory and radiological investigations. It is extensively illustrated and the reproductions are excellent.

The Middlesex Hospital (1745-1948)

HILARY ST. GEORGE SAUNDERS. London: Max Parrish. 1949. Pp. 100. 8*s.* 6*d.*

THE Middlesex Hospital has done well to chose Mr. Hilary St. George Saunders to chronicle its two hundred years of growth and achievement, and his practised pen gives to a story, certain to be read with interest by Middlesex men, a very much wider appeal. It is the story of a triumph of the voluntary system. Middlesex Hospital, unlike St. Thomas's or St. Bartholomew's, has no past stretching far back into the history of England; nor had it, like Guy's, a wealthy godfather to speed it on its way with a rich endowment. From its beginning in two little houses (which survive to this day) in Windmill Street off the Tottenham Court Road, it simply grew, not without difficulties and setbacks but with an ever-increasing momentum. That it did so was due, even more than at other hospitals whose resources were greater, to the unremitting labours of a staff that not only wrought in the hospital but wrought the hospital itself. Charles Bell, Bland-Sutton, Webb-Johnson, and a host of others not only gave voluntarily to their hospital a life-time of service in its wards and classrooms; they saw to it that money was always forthcoming for its unending extension. Middlesex Hospital has never lacked benefactors and benefactions on the largest scale. To read its story is to appreciate the boldness of the reforms of today. The staff of tomorrow, salaried and equipped at all points by the State, must keep the pace set by men who were, and knew themselves to be, the architects of its greatness.

[1] See *Lancet*, 1949, ii, 848.

that preformed stores of esterase are held in the liver and released in response to alterations in plasma-albumin levels,[19] the liver being the site of synthesis.[20] The blending of many of these enzyme-protein-disease relationships is a pleasing feature of WATERLOW'S study.

The metabolic effects of the low esterase levels are unknown. The hydrolysis of acetylcholine or fatty acid esters may be affected. The esterases, along with some other enzymes formerly considered to be concerned only with hydrolysis, have now been allotted rôles in anabolic reactions.[21] In the future, therefore, they are likely to be accorded greater importance in studies of the lean and hungry tissue cells of malnourished people.

Deoxycortone and Pregnenolone in Rheumatism

WHEN LEWIN and WASSÉN[22] announced that deoxycortone and ascorbic acid benefit patients with rheumatoid arthritis, their work was widely repeated. At first the favourable reports were as numerous as the unfavourable, and they included some experimental data. But the presentation of negative findings is always an ungrateful task, and many physicians who had no success with the method did not say so. The view of the large majority is that expressed by twelve medical members of the Empire Rheumatism Council,[23] and several detailed papers we have printed in the last few weeks show that if deoxycortone with ascorbic acid has any pharmacologically valuable effects they are obtained only irregularly and do not produce objective changes that can be readily measured. Though a remarkably large number of clinicians have from time to time noted improvement which they regarded as significant, it has always been difficult, on the theoretical side, to see how the intramuscular injection of a very small quantity of hormone in oily solution, could be responsible for any substantial change in rheumatoid arthritis within a few minutes. Undoubtedly 'Cortisone' and adrenocorticotropic hormone can remove the symptoms, but the improvement seems to take much longer than the 5–15 minutes claimed for deoxycortone. Moreover the quantities of cortisone needed are much greater than the quantities of deoxycortone which have been used; and even if some theoretical mechanism could be devised for the conversion of deoxycortone into cortisone, it is not clear why 5 mg. of the former should have an effect comparable to 100 mg. of the latter. Deoxycortone and ascorbic-acid therapy came in for further condemnation from E. C. KENDALL and PHILIP HENCH at the National Academy of Sciences last month.[24]

When the effects of cortisone and A.C.T.H. were first described, it was pointed out that their importance lay chiefly in the stimulus they would give to research; and this has of course been borne out. Deoxycortone and ascorbic acid is one attempt, and probably an unsuccessful one; the latest seems to be the use of pregnenolone. Two papers have lately been published by DAVISON et al.[25] and by FREEMAN et al.[26] describing improvement with pregnenolone in cases of rheumatism. The claims, though very definite, are less than those made for deoxycortone by some of its supporters. The improvement is much slower and the quantites used are much more of the same order as required for cortisone. Pregnenolone is more easily obtainable than cortisone, and if these claims are substantiated this drug should be another very useful tool. However, KENDALL and HENCH, at the same meeting,[24] denied that pregnenolone has any action on rheumatoid arthritis or any of the other ills which respond to cortisone. They also said that a number of other compounds related to cortisone were without effect.

The position therefore still is that no substances except cortisone and A.C.T.H. can yet be held to have substantiated their position in the endocrine treatment of rheumatism.

Annotations

MEDICINE IN AUSTRALASIA

Prof. G. W. Pickering, who last year held the Sims Commonwealth travelling professorship, brought home more than casual impressions; for his report[27] contains an acute analysis of the university systems in Australia and New Zealand. He detected two fundamental weaknesses. The first was the absence of a body analogous to our own University Grants Committee, which "is sensitive enough to interpret university needs without undue delay, and which provides for financial assistance on a relatively generous scale from the Government, while at the same time insulating the universities from purely political pressure." In New Zealand this defect was being remedied by the establishment of such a committee; but in Australia there was no promise of such a reform, and in some places there was a distinct tendency for the State to interfere in university affairs. This may be partly ascribed to the composition of the Civil Service. Professor Pickering later visited South and East Africa: and he points the contrast between Civil Servants in Colonial territories, who have nearly all been recruited from universities, and those in the Dominions, who have mostly risen by reason of long experience and ability after entering the service on leaving school. In the Dominions "the universities were very poorly supported financially and had to settle many of the smallest details of their programmes with Civil Servants who had no real knowledge of the function or purpose of a university." The second main defect to which Professor Pickering draws attention is the lack of integration, in both New Zealand and Queensland, between the teaching hospital's board of management and the medical school. In New Zealand the members of the board are elected as representatives of local districts, the views of the staff being *voiced* by the medical superintendent. Thus neither expert knowledge nor continuity of policy is assured: and with a change in the board's membership, a senior physician or surgeon may be dropped from the staff, to be reappointed after a year or two to a junior post.

In most of the Australian States the university must accept all students qualifying for admission; and this has led, since the war, to gross overcrowding, notably deemed to have the ability, the willingness, and the facilities for teaching, we could still provide a reasonable choice of trainer and locality of training.

[27] Report to the presidents of the Royal College of Physicians of London, the Royal College of Surgeons of England, the Royal Australasian College of Physicians, and the Royal Australasian College of Surgeons.

The report contains much else to commend, for it covers a large field. "The Committee has formed the view that the attainment and maintenance of a high standard of general practice demands, firstly, a period of systematic postgraduate preparation, and secondly, the opportunity for continuing education throughout the period of active practice." With so wide a range of studies to provide, all is grist that comes to the mill, and each chapter has its quota of thought-provoking ideas. Not all, of course, are new; but even the old ones have often been given a new look and adapted to the new patterns of general and hospital practice. Many of these ideas could be applied in the absence, or in advance, of agreement about the three years' preparation for practice. Prominent among these are the suggestions for developing the office of postgraduate dean, with special emphasis on his value as a director of students (in non-teaching hospitals, and with selected practitioner trainers, as well as in teaching hospitals), to his rôle of adviser to the newly qualified, and to his function of planning postgraduate instruction for established practitioners, whether by lectures, demonstrations or films, or by arranging clinical assistantships or other personal association with medical teaching. Particulars are given, too, of lectures on general practice, which are already being given by a general practitioner to the students in at least one teaching hospital. These lectures could profitably be copied elsewhere.

Enzymes, Proteins, and Malnutrition

ONE of the reasons for the increasing interest in *medical research in our African colonies* has been "the rapid advance in the knowledge of nutrition, and the recognition not only that the colonial territories offer unique opportunities for gaining new information on this subject, but also that defective nutrition is one of the main causes of inefficiency, ill-health, and general backwardness in tropical countries."[1] Since 1946 a Medical Research Council unit have been carrying out an experiment in applied nutrition in the Gambia, British West Africa, as part of the scheme to improve the nutrition of this group of colonial peoples.[2–5] One of the difficulties is that the food-supply, like the rainfall, is markedly seasonal; and just at the time of the year when food-supplies are running out the Gambian has to make special efforts to produce another year's crops. His diet is not likely to be well balanced in the seasons of comparative plenty, but in these half-yearly "hungry-gaps" it is always unbalanced as well as generally insufficient. Moreover, besides those to meet his body's physiological demands, the Gambian requires extra nutrients for the production of antibodies against the many infections and infestations to which he is exposed; this call may be so urgent and insistent that the tissues become impoverished and, though immunological response seems adequate, death may ensue. The need for nutrients is at its highest during growth, particularly in infancy; so it is hardly surprising that about half the children born die before they reach the age of ten years.[3]

The scientific value of the arrangements whereby research-workers from this country can from time to time employ their tools and techniques in tropical countries was illustrated in Dr. JOHN WATERLOW's paper of May 13 (p. 908). In malnourished African infants he showed that the interplay of dietary and zymotic factors may produce clinical manifestations of protein insufficiency, accompanied by early histological signs of liver damage and by subnormal levels of plasma albumin, plasma esterase, and liver esterase. In growing animals the enzyme contents of the tissues are known to depend on age and feeding. The plasma-esterase levels tend to be low at birth and to rise during growth—puppies seem to derive their plasma esterase from the milk or colostrum of the dam—and chronic malnourishment may prevent this normal rise occurring.[6] Thus at birth the rat has no measurable amount of xanthine oxidase in the liver, whereas at weaning it normally has about half the adult amount, and the increase after weaning depends on the diet.[7] More than a dozen liver enzymes are known to be reduced in amount or activity when underfeeding or starvation has lowered the protein content of the liver.[8]

The observation that the tributyrin-esterase activity of serum is lowered in cachectic conditions was first made by BAUER[9] in 1912; and many times since it has been shown that similar conditions interfere with the normal hydrolysis of acetylcholine.[10] It seems that the same enzyme may hydrolyse the esters of fatty acids and acetylcholine, for highly purified preparations of cholinesterase retain their power to *hydrolyse tributyrin*.[11] Plasma albumin levels may be seriously lowered by lack of dietary proteins,[12] and in various pathological states the amount of cholinesterase in the plasma has been shown to vary directly with the amount of albumin[13] (except in some cases of kidney damage when there is albuminuria but the esterase does not pass through the kidney filter[14]). Reduction in the cholinesterase activity of the plasma has been shown to be associated with liver damage in infectious hepatitis and cirrhosis[15]; with underfeeding[16]; and with deficiency of liver proteins.[17] In spite of the close correspondence between the changes in albumin and esterase in the plasma, the esterase is not contained in the albumin fraction but in a fraction composed mainly of α_2 globulin.[18] It is believed

that preformed stores of esterase are held in the liver and released in response to alterations in plasma-albumin levels,[19] the liver being the site of synthesis.[20] The blending of many of these enzyme-protein-disease relationships is a pleasing feature of Waterlow's study.

The metabolic effects of the low esterase levels are unknown. The hydrolysis of acetylcholine or fatty acid esters may be affected. The esterases, along with some other enzymes formerly considered to be concerned only with hydrolysis, have now been allotted rôles in anabolic reactions.[21] In the future, therefore, they are likely to be accorded greater importance in studies of the lean and hungry tissue cells of malnourished people.

Deoxycortone and Pregnenolone in Rheumatism

When Lewin and Wassén[22] announced that deoxycortone and ascorbic acid benefit patients with rheumatoid arthritis, their work was widely repeated. At first the favourable reports were as numerous as the unfavourable, and they included some experimental data. But the presentation of negative findings is always an ungrateful task, and many physicians who had no success with the method did not say so. The view of the large majority is that expressed by twelve medical members of the Empire Rheumatism Council,[23] and several detailed papers we have printed in the last few weeks show that if deoxycortone with ascorbic acid has any pharmacologically valuable effects they are obtained only irregularly and do not produce objective changes that can be readily measured. Though a remarkably large number of clinicians have from time to time noted improvement which they regarded as significant, it has always been difficult, on the theoretical side, to see how the intramuscular injection of a very small quantity of hormone in oily solution, could be responsible for any substantial change in rheumatoid arthritis within a few minutes. Undoubtedly 'Cortisone' and adrenocorticotropic hormone can remove the symptoms, but the improvement seems to take much longer than the 5–15 minutes claimed for deoxycortone. Moreover the quantities of cortisone needed are much greater than the quantities of deoxycortone which have been used; and even if some theoretical mechanism could be devised for the conversion of deoxycortone into cortisone, it is not clear why 5 mg. of the former should have an effect comparable to 100 mg. of the latter. Deoxycortone and ascorbic-acid therapy came in for further condemnation from E. C. Kendall and Philip Hench at the National Academy of Sciences last month.[24]

When the effects of cortisone and A.C.T.H. were first described, it was pointed out that their importance lay chiefly in the stimulus they would give to research; and this has of course been borne out. Deoxycortone and ascorbic acid is one attempt, and probably an unsuccessful one: the latest seems to be the use of pregnenolone. Two papers have lately been published by Davison et al.[25] and by Freeman et al.[26] describing improvement with pregnenolone in cases of rheumatism. The claims, though very definite, are less than those made for deoxycortone by some of its supporters. The improvement is much slower and the quantites used are much more of the same order as required for cortisone. Pregnenolone is more easily obtainable than cortisone, and if these claims are substantiated this drug should be another very useful tool. However, Kendall and Hench, at the same meeting,[24] denied that pregnenolone has any action on rheumatoid arthritis or any of the other ills which respond to cortisone. They also said that a number of other compounds related to cortisone were without effect.

The position therefore still is that no substances except cortisone and A.C.T.H. can yet be held to have substantiated their position in the endocrine treatment of rheumatism.

Annotations

MEDICINE IN AUSTRALASIA

Prof. G. W. Pickering, who last year held the Sims Commonwealth travelling professorship, brought home more than casual impressions; for his report[27] contains an acute analysis of the university systems in Australia and New Zealand. He detected two fundamental weaknesses. The first was the absence of a body analogous to our own University Grants Committee, which "is sensitive enough to interpret university needs without undue delay, and which provides for financial assistance on a relatively generous scale from the Government, while at the same time insulating the universities from purely political pressure." In New Zealand this defect was being remedied by the establishment of such a committee; but in Australia there was no promise of such a reform, and in some places there was a distinct tendency for the State to interfere in university affairs. This may be partly ascribed to the composition of the Civil Service. Professor Pickering later visited South and East Africa: and he points the contrast between Civil Servants in Colonial territories, who have nearly all been recruited from universities, and those in the Dominions, who have mostly risen by reason of long experience and ability after entering the service on leaving school. In the Dominions "the universities were very poorly supported financially and had to settle many of the smallest details of their programmes with Civil Servants who had no real knowledge of the function or purpose of a university." The second main defect to which Professor Pickering draws attention is the lack of integration, in both New Zealand and Queensland, between the teaching hospital's board of management and the medical school. In New Zealand the members of the board are elected as representatives of local districts, the views of the staff being voiced by the medical superintendent. Thus neither expert knowledge nor continuity of policy is assured: and with a change in the board's membership, a senior physician or surgeon may be dropped from the staff, to be reappointed after a year or two to a junior post.

In most of the Australian States the university must accept all students qualifying for admission; and this has led, since the war, to gross overcrowding, notably in Sydney. "To me, the overriding consideration is quality . . . for once it is lost, it is not easily regained. There is therefore an upper limit of entry which all universities should be empowered to enforce." In undergraduate teaching methods Professor Pickering found much to applaud. Thus in New Zealand the professor of bacteriology and preventive medicine allocates to each pair of students a problem to be worked out during the long vacation of the fifth year; and at Adelaide the mammalian-physiology class is divided into teams of about six who conduct a series of experiments on wild rabbits, one student acting as anæsthetist, one as surgeon, and another as assistant, while two look after the recording and one keeps the records. In Australia the young graduate may face difficulties unknown in this country; for in some States resident posts are exceptional outside the capital cities. "It will be to the local interest of the hospitals themselves, and vital to the national interests, that resident posts be established in all hospitals with 100 beds and over." For the slightly more senior man at the critical registrar phase the position is even more difficult. Registrar posts are few and the only full-time university units with junior posts are at Sydney and Dunedin. To gain experience, many of the best men come to this country; and some are then lost to the Dominions because there are not enough good jobs to attract them back. Professor Pickering was "rather appalled" by the prevalence of "diplomatosis" among the young graduates of the Dominions; but "I doubt if we on this side can do much to alter this, except by avoiding any increase in the already formidable list of postgraduate diplomas, and if possible eliminating most."

In New Zealand, Professor Pickering was not very deeply impressed with university standards: "the Universities have been regarded too much in the past as teaching institutions and too little as institutions for the pursuit of knowledge by research." Yet the standard of medical practice is high. "In Timaru, a small provincial town, the standard of case presentation and the intelligence of the questions asked after my lecture was as high as one would have obtained in a teaching hospital, and far beyond what one would meet in a provincial town of comparable size at home." The payment by the State of a flat-rate for each consultation tests the doctor's integrity; and "it says a great deal for the New Zealand character that there is still the same urge to excellence, and the same desire to come home for postgraduate work, despite the immediate financial prospects." While in New Zealand, Professor Pickering watched dental nurses doing their work of filling and extraction among school-children. "The parents like them and the children like them. Moreover the dentists like them, for the work they do is monotonous and unremunerative to the dentist, and when he receives the patients as adults, the groundwork has been well laid."

From this urbane report it is clear that the mother country has no less to gain from the example of the Dominions than she can offer in return.

STANDARDS IN ADVERTISING

The Code of Conduct Committee of the advertising profession has now issued a revised edition of its Code of Standards in relation to the Advertising of Medicine and Treatments. This code, originally drawn up in 1948, is recognised on the one side by the Newspaper Proprietors Association, the Newspaper Society, and the Periodical Proprietors Association, and on the other side by the Proprietary Association of Great Britain, the Advertising Association, the Incorporated Society of British Advertisers, and the Institute of Incorporated Practitioners in Advertising; so its provisions apply to almost all the major national and local newspapers and magazines, and to m st of the large firms. In its list of medicines, treatments, products, or appliances which may not be advertised the code goes further than statute law, and the conditions listed in the new edition include asthma (unless the advertisement makes it clear that the product does no more than alleviate an attack, and recommends the sufferer to seek medical advice), amenorrhœa, "artery troubles," arthritis, pernicious anæmia, blood disease, "blood-pressure," cardiac symptoms, dermatitis, chronic or persistent indigestion or rheumatism, varicose veins, "slimming" (this last does not apply to offers of physical-exercise courses or articles used for exercise). Though still not assuring accuracy in advertisements, this new edition is on the whole an advance on the first, issued two years ago.[1] The committee included representatives from the British Medical Association and the Pharmaceutical Society, sitting as members of the Advertising Association.

WAYS WITH OLD PEOPLE

Care of the aged presents a wide field, recently untilled, but now under cultivation by a growing body of enthusiasts inspired by some keen pioneers. The crop is still uneven, certainly; but it is healthy and variegated. Dr. Marjory Warren, speaking at a conference on the better care of the elderly, arranged by the Salford public-health department during May, dwelt on the value of this variety. Everyone agrees, she said, about continuity in the treatment of old people: we must continue to look after them until they require no further treatment; but different units must be allowed to choose their own ways of setting about it. Dr. E. B. Brooke, of St. Helier Hospital, Carshalton, who also spoke at the conference, aims at giving patients all the benefits of hospital care in their own homes. He was supported by Dr. J. M. Greenwood, of Withington Hospital, Manchester, who said that for some four months he had been seeing every patient listed for admission to a chronic sick ward; about a quarter of them, he found, did not need hospital care. Dr. Warren herself at the West Middlesex Hospital, was the first person to start a unit in which old people were classified and treated. The Minister of Health, in a new circular[2] on the treatment of the elderly chronic sick, does not urge any standard pattern on the hospital authorities but is content to draw attention to some underlying principles. Thus early investigation and accurate diagnosis should be ensured and suitable treatment arranged; admission to chronic wards should always be by way of wards or hospitals for acute cases; and reablement for the chronic sick should be better and more general than it is now. Patients who are not fit to be discharged to their own homes or to local-authority residential homes, but who no longer need active treatment, should be placed in a separate part of a large hospital, or in special hospitals, or in long-stay annexes attached to an acute hospital. Every encouragement should be given to the treatment of old people in their own homes by the general practitioner, acting when necessary in conjunction with the domiciliary specialist services or hospital outpatient departments.

This outline offers scope for experiment of the many kinds discussed at the conference. As Dr. [illegible] noted, the hospital ward can offer me… diagnostic facilities and treatment (esp… therapy), nursing care, medicosocial… meals, heating, and a bed with … some of these benefits can be … by means of a ferry service … can be provided from … notably the home-… local authority. … offer quite a w…

pplemented if necessary by taking the patient daily to e physiotherapy department in transport provided y the hospital. A domiciliary laundry service is being veloped, with the help of the Assistance Board. ort spells in hospital are arranged for those who ed investigations or treatment which cannot be underken in their homes, for those in the terminal phase of n illness distressing to relatives, and for those whose latives are badly in need of a rest.

Dr. Greenwood divides the care of old people into the reventive and curative aspects. The first is a medicoocial problem, and he places suitable housing high on is list of our needs; he also advocates education of the ublic, employment of old people, and the provision f such things as old people's clubs. On the curative ide he is discontented with bedridden old people; we nust get them up, stimulate them mentally and physically —even to the point of bullying them in mild ways. Dr. Warren sees the patient and his disorders and his personal difficulties as a single problem, and sets about solving this quadratic equation with something like gusto. The physician must take a full clinical history, past and present, from the patient and his friends, examine the old person thoroughly, take a history of his social conditions, and plan his treatment in association with the health-visitor and the medicosocial worker or almoner. Her general principles of treatment aim at activity, independence, and some assurance of security for the patient, and a future in an atmosphere of hopefulness and happiness. Specific treatment, of course, is relevant to the disease or diseases, and may call for adaptation of orthodox methods. The happy days of "dumping" are gone, she says—which the more lazy among us, looking forward to a strenuous old age, may be tempted to regret. The reabled old, however, getting up and walking after years in bed, seem to think well of the change.

"COMICS"

THOUGH controversy concentrates on the effects of the cinema on child audiences, some other characteristic twentieth-century influences have not been forgotten. In the United States, where millions of adults as well as children show addiction to the comic strip, the matter and symbolism of the "comic" convention, and the extraordinary response that it seems to evoke in the adult public, are examined in an angry but informative and entertaining little book by Legman.[1] Collecting a series of peculiarities of this form of commercial art, he records that in a girl's periodical, within a few weeks, brides in their wedding dresses were dumped in the mud on no less than seven occasions; and on a basis of one such picture per page, he calculates that by adolescence the American child will have absorbed something like 18,000 sadistic pictures. Attempts to provide better motives and loftier themes have been revealingly unsuccessful, though there have been Biblical and religious comics, one of which was largely devoted to the tortures inflicted on martyrs. As a result of protests, including a particularly strong one from Wertham, whose experience of the psychiatric aspects of
nt crime is among the longest in the United States,
first desc lately been a certain change of front: a recent

t love is probably
to the censors
reaking Point have always shown themselves more tolerant to blows than to kisses; they "see thousands of pictures in comic-books of half-naked women being tortured to death, and complain only that they are half-naked. . . . Comic-books do not exist in a vacuum. American parents see nothing wrong with the fictional violence of the comic-books because they are themselves addicted to precisely the same violence in reality. . . . At least sex is normal: is murder?"

The vigour of this polemic is somewhat blunted for readers in a society where addiction to comics is less intense and where some of the native productions maintain a high standard of homely fun. In issuing a new English comic to compete with imported varieties, the Hulton Press seem to have taken no chances of becoming involved in a similar controversy. The editor is a clergyman, and the matter, like that of Dick Barton, is based on a nicely adjusted distinction between violence which is sadistic and violence which releases "healthy aggression." Besides a good deal of information about the inside of locomotives and of germinating seeds, this comic produces heroes who are scrupulous in finding socially acceptable outlets for their two-fistedness. One flies to Venus in a rocket, at the behest of World Government, to find new means of growing food for an overpopulated world. Others organise international espionage to secure the atom bomb against international crooks, being at pains to point out that such an arrangement is to everyone's advantage, on both sides of the Iron Curtain. On the back page we find the voyages of St. Paul. While not meeting Legman's criticisms of violence as a sexual substitute (it could hardly be expected to do so) the Hulton publication balances itself fairly well between edification and blood-and-thunder on the assumption that the second does not necessarily have to be frankly unedifying. It is the streak of psychopathology which is alarming in the American article, and this at least is avoided. The Jeremiahs who denounced Sweeney Todd or the Steam Man as subversive of youth had not the same strong reason as those who now denounce Superman and the Katzenjammer Kids—namely, that our generation has seen similar patterns of fantasy realised elsewhere than on paper, and has found them singularly uncongenial.

GERMAN PSYCHIATRY REVIVED?

THE prominent part played by German-speaking workers in Germany, Austria, and Switzerland in the development of psychiatry during the last fifty years is familiar to us all. The names of Kraepelin, Wernicke, Freud, Wagner-Jauregg, Bleuler, Bonhoeffer, and Kretschmer stand for a high tradition maintained until the Nazis came to power. From that time psychiatry was especially misused for political purposes—to excuse the introduction of compulsory sterilisation, and later the systematic extermination of chronic and incurable patients. Expulsion and suppression of workers for racial and political reasons under Hitler's Reich was followed, twelve years later, by fresh expulsions for opposite political reasons when Hitler's Reich broke down.

How much of the solid structure of this branch of medicine has survived the storms and upheavals of the last fifteen years? And how far has the standard of German published work been preserved? A few publications which have recently reached Great Britain give some idea. Some characteristic schools of thought and methods of approach have survived. Kleist, of Frankfurt University, for instance, who as early as 1919 broached the theory of the heredo-degenerative nature of certain psychoses, has published his latest contribution in one of the reports issued by the U.S. Military Government in Germany.[1] This describes a follow-up of cases,

and ends by summing up earlier studies by Kleist's pupils. The grouping and subgrouping of mental illness according to symptomatic differences is carried to extremes (ten different types of paranoid schizophrenia are distinguished); and the whole suggests a relapse into the purely symptomatic classifications of the 19th century.

Descriptive clinical psychology, prominent in German psychiatry before Hitler, is well represented in a small monograph by Weitbrecht on convulsive therapy.[2] He analyses sensitively and well the influence of this form of physical treatment on the symptoms and course of psychoses. This influence, he considers, is not merely one of negation and extinction of symptoms: there is a subtle interplay between the original personality and the mechanisms of illness and therapy, leading to replacement and adaptation of symptoms. He observes and describes with as little theoretical interpretation as possible, and throws light on the psychology of the psychosis as well as on the effects of the therapy.

Schultz-Hencke's textbook on dream analysis[3] is an example of the undaunted thoroughness of Teutonic workers. Starting with a philosophy of human instincts, he works through all the explanations he can put forward of the dream as a psychological phenomenon, and arrives at a table of model dreams; and then by applying his psychology of drives to the same dream sample in different settings, he offers many possible interpretations of each model. Though the book is based on Freud's concepts, it is written obscurely, with many digressions; it lacks the clear observation-close-to-life that distinguishes Freud's writings. More practical, but rather superficial, with a flavour of lay and nature medicine, is a small volume on treatment by active relaxation written by Dr. Faust.[4] Like Jacobson, in America, he trains patients with neuroses and psychosomatic disorders to relax deliberately for the relief of muscular and mental tension. His mixture of naïve—and in places rather cranky—theory with sound practical advice is typical of this kind of book wherever it appears. Relaxation as an adjunct to psychotherapy, however, has been adopted by such well-known authorities as J. H. Schultz[5] and Kretschmer.[6]

K. Scheele,[7] a surgeon, discusses in simple language the common fears and concerns of the patient during examination, before and after operation, and in hospital surroundings; and some problems of pain and anæsthesia, convalescence, disfigurement, and compensation. The booklet, meant for the student or young medical man, often refers to the similar, more comprehensive clinical psychology, by Hellpach,[8] which has recently appeared in a second edition.

Finally, Hitler involuntarily enriched psychiatric literature by forcing two outstanding academic teachers to their writing tables by suppressing their other activities: Karl Jaspers,[9] the eminent philosopher, has revised his *General Psychopathology,* first published in 1913—a book which has contributed much to clear thought on psychiatry. An English translation of the new edition, now being prepared in America, will be welcome to British psychiatrists. The second work is *Verstehende Psychologie,* the psychology of empathy, by H. W. Gruhle,[10] who has recently been appointed to the chair of psychiatry at Bonn. It records his life work,—and deals with the problem of psychological understanding between human beings, analysing its criteria and its fallacies. It is crowded with original observations, and draws on the sister sciences of psychology, history, and sociology. It is free from theoretical bias and does not take refuge in psychology without psyche. These two books by old-timers challenge modern German psychiatry to regain and retain its former standard.

TOWARDS SAFETY IN BOXING

IN most games and competitive sports the risk of sprains, fractures, or even visceral damage is accepted as inevitable; indeed, the element of danger is itself an attraction. But boxing is unique in that the chief aim of the contestant is to disable his opponent; and though his intention is to produce only temporary disablement he may easily go further than he intends. The head is the principal target; and, though facial bruises and abrasions can usually be dismissed as trivial, no fewer than 36 reported fatalities from intracranial hæmorrhage, caused either by a blow or a fall, have been collected by Jokl.[1] Other serious injuries include the curious condition known as punch-drunkenness, which seems to be the result of repeated trauma causing multiple hæmorrhages in the deeper portions of the cerebrum, the corpora striata, and the corona radiata, which are later replaced by gliosis leading to a state mimicking parkinsonism. Blows over the precordium may result in direct damage to the heart, and reflex vagal stoppage in diastole has been caused by blows in various situations. The solar-plexus knockout, though very unpleasant, rarely does much harm, but visceral lesions have occasionally been noted. Among more remote consequences may be included the activation of latent tuberculosis and other pre-existing diseases.

Jokl, who is an enthusiast on the subject of exercise and certainly no alarmist, has been sufficiently impressed by these catastrophes to advocate the exclusion of boxing from the physical-training programme of Armed Forces. The customary reply, of course, is that the casualty-list of this sport is small compared with that of certain other sports, especially when one considers that so many men take part in it in so many parts of the world. But clearly some solicitude is justified, and it is interesting to hear that the medical advisory board of the New York State Athletic Commission has lately announced a new set of medical rules and regulations for boxers and wrestlers who participate under its jurisdiction.[2] In future all contestants are to be medically examined just before a bout; and for championship matches a further special examination five days previously will be required. During bouts, an attending physician at the ringside may enter the ring to evaluate apparent or latent injury, and when in his judgment the contestant is in serious danger he shall advise the referee to end the contest.

In principle such recommendations will be approved; but whether they will really be much of a safeguard or can be fully applied in practice, is less certain. Sir Adolphe Abrahams[3] has deprecated the conventional examination of competitors before a marathon race on the ground that the only danger of this event is hyperpyrexia, and that the doctor is unlikely to identify those competitors constitutionally liable to overheating. In the same way clinical examination merely to exclude gross physical signs is generally a farce in the case of pugilists; and what sort of examination could identify the likely candidates for intracranial hæmorrhage? Frequent neuropsychiatric investigations might reveal early warning symptoms of traumatic encephalopathy, but innate personality traits can readily be confused with it. As for the medical attendant at the ringside, it may be easy enough for a referee to use his prerogative to end a contest when the indication is unmistakable—for example, when there is an injury to the eye and consequent blindness—but he would need most convincing testimony from a doctor to persuade him on less obvious grounds. The recovery of a boxer from extreme distress is a commonplace experience, for the reserve called upon in extreme urgency is inestimable. If the referee is to be under an obligation to accept a medical opinion, one can well imagine that a doctor, especially when he knows that much money and other important considerations are at stake, will hesitate to take a course of action which may be reprobated as premature or unjustified.

The chairman of the medical advisory board of the New York State Boxing Commission expresses the hope that the new regulations will safeguard the health of the athletes concerned and will reduce accidents before, during, and after bouts. We shall all share this hope, though it remains to be proved whether the precautions now proposed will be more effective in practice than those ordinarily enjoined by common sense.

LOSS OF INFANT LIFE

THE general downward trend in the birth-rate since the beginning of the century has been accompanied and to some extent offset by a decline in the stillbirth and infant-mortality rates; but of course we have by no means reached the limit of achievement in the saving of infant lives. The biological and medical committee of the Royal Commission on Population collected much evidence on reproductive wastage due to abortion, stillbirth, and infant mortality, reproductive capacity and the birth-rate, and involuntary childlessness; and they have now published[1] the reports on this evidence which they made to the commission.

As a cause of loss of infant life, abortion is difficult to assess, because most induced abortions are illegal, and both field surveys and hospital studies are therefore liable to underestimate the proportion of them. The incidence of spontaneous abortion is almost as difficult to estimate, but the committee incline to put it in the region of 7·6% of all pregnancies: and they suggest that therapeutic abortions amount to about 0·7%. It is not easy to find ways of reducing the numbers of illegal abortions, but it is thought that they would undoubtedly decrease if people were more aware of the danger this practice carries to the mother's health (apart from her life) and her future capacity to bear children. "The decision to have an abortion is seldom reached by the mother alone, and it is important that the father also should be aware of these dangers."

The reasons why women seek illegal abortion are social rather than medical or biological, and it therefore stands apart from other causes of loss of infant life. But taking it into account as well as they can the committee put the reproductive wastage as a whole in England and Wales between 15% and 22% of all children conceived. For the other causes of wastage they can give exact figures: stillbirths account for the loss of 2·3% of all children conceived, neonatal death for 2·0%, and deaths between four weeks and one year for 1·4%—a total of 5·7%. When cases are grouped according to the Registrar-General's five social classes, there is a steady increase in the stillbirth-rate with falling social class. The nutrition of the mother during her own childhood and her pregnancy, her living conditions, the care she receives before and after the birth, and the skill with which she is delivered may all have a bearing on this trend. Birth injuries, especially to premature children, could be avoided by more skilful delivery and by the elimination of unnecessary interference during labour. That skilful obstetrics really does save lives is shown by the fact that in 1939 the stillbirth-rate in primiparæ in social classes I and II (the classes where the infants are likely to be strong because the mothers are in the main healthy and well nourished) was 37 per 1000 births, but among 1633 primiparæ belonging to these classes supervised by specialists the rate was only 17. The committee conclude that, in spite of a considerable fall, attributable to better feeding, in the stillbirth-rate in recent years, it could be reduced still further by better obstetrics, including more thorough antenatal care, and better nutrition and living conditions for the poorer mothers. Even the present rate of 23 might be reduced to 18 per 1000 or even less, and this would mean a saving of 4000 babies yearly.

The picture is much the same for neonatal deaths: again there has been a considerable decline in the rate (from 30 per 1000 in 1937 to 20 in 1948), and again the rates rise as the social class descends. Post-mortem studies show that birth-injury, congenital abnormalities, and postnatal infection take the chief toll, especially of premature children—who make up no less than half of those who die in the first four weeks of life. The most promising method of reducing neonatal deaths would therefore be to prevent premature births—by better nutrition of mothers, better antenatal care, good housing, economic security (so that the mother will not have to do heavy work during pregnancy, even in her own home), and family planning so that children are properly spaced. At this age bronchitis and pneumonia are the infections most commonly causing death, while in children between four weeks and a year enteritis and diarrhœa are more commonly responsible, especially in classes III, IV, and V. Chemotherapy has greatly reduced all death-rates from infections since 1941, but they could be brought still lower, the committee think, by better teaching of health conditions to children in schools, more and better health visiting, better child-welfare services, and better training of health visitors, midwives, and medical students in infant and child health, preferably in schools set up for the purpose. By means of all measures taken together, they believe, it would be possible, without any new progress in medical knowledge, to bring the infant-mortality rate down from 34 to perhaps 14 per 1000—which, in 1948, would have meant a saving of 11,000 lives in England and Wales. But whether this saving would have meant a like increment to the population is another matter: some parents decide on the size of their family in advance, and the saving of a child in such a family would probably mean deliberate avoidance of a conception later. Leaving this possibility out of account, the committee suggest that if reproductive wastage was reduced to the extent they think possible, the rate of recruitment to the population would gain by about 1·5%. On the evidence before them, they could not see that there had been any noteworthy decline in the reproductive capacity of the nation, and they concluded that the reduction in the average size of the family since the 1870s has been very largely due to deliberate family limitation.

Involuntary childlessness has only recently begun to be studied. The committee estimate that it occurs in some 5–8% of marriages, the main causes—accounting for half to two-thirds of the cases—being defective spermatogenesis (in about a third of the marriages), blocked fallopian tubes (in 19% of 2291 women examined), and failure to ovulate (in 17% of 1253 women examined). Some miscellaneous causes include inability to achieve coitus, uterine abnormalities, ignorance of the fertile phase, dietetic deficiency, and lack of confidence. More research is clearly needed on every aspect of this problem, but in the meantime people need, and are eager to receive, simple sex instruction at the time of their marriage, and adequate investigation on modern lines when they seek advice about subfertility from their doctors.

TRAINING FOR GENERAL PRACTICE

REPORT BY A B.M.A. COMMITTEE

IN *The Training of a Doctor*[1] a committee of the British Medical Association gave their views on the medical curriculum. Now another B.M.A. committee, sitting under the same chairman, Sir HENRY COHEN, F.R.C.P., have considered the postgraduate training of the general practitioner, and have reported.[2] The members are: Sir LIONEL WHITBY, F.R.C.P., Dr. C. W. C. BAIN, F.R.C.P., Dr. E. A. GREGG, Dr. J. A. BROWN, Mr. A. M. A. MOORE, F.R.C.S., Mr. A. LAWRENCE ABEL, F.R.C.S., Dr. JANET K. AITKEN, F.R.C.P., Dr. J. T. BALDWIN, Dr. G. W. BAMBER, F.R.C.P., Dr. G. O. BARBER, Sir ALEXANDER BIGGAM, F.R.C.P., Mr. NORMAN CAPENER, F.R.C.S., Mr. V. ZACHARY COPE, F.R.C.S., Dr. H. GUY DAIN, F.R.C.S., Dr. HUGH DAVIES, D.M.R.E., Dr. R. G. GORDON, F.R.C.P., Dr. K. H. C. HESTER, F.R.C.S., Dr. R. P. St. L. LISTON, Prof. HILDA N. LLOYD, F.R.C.O.G., Mr. J. D. McLAGGAN, F.R.C.S., Miss IDA MANN, F.R.C.S. (resigned, July, 1949), Dr. J. I. MILNE, Dr. CHARLES NEWMAN, F.R.C.P., Sir PHILIP PANTON, Sir LEONARD PARSONS, F.R.C.P., F.R.S., Dr. I. C. B. PEARCE, Dr. C. M. SEWARD, F.R.C.P., Dr. DONALD STEWART, F.R.C.P., Mr. J. W. TUDOR THOMAS, F.R.C.S., Dr. C. W. WALKER, Prof. B. W. WINDEYER, F.R.C.S., and Prof. G. M. WISHART, F.R.F.P.S.

The committee regard general practice as a special branch of medical practice requiring an adequate period of training under supervision, and continuous education throughout the doctor's life; and they believe that the conditions of his life should be adjusted to give him leisure enough to interest himself in such education.

General Practice

The change chiefly affecting general practitioners in the past century has been the growing bulk of medical knowledge. In the early 19th century doctors could be conversant with almost the whole range of medical knowledge; but in our own century it has become impossible for one man to practise or comprehend in detail the whole field of medicine, or to possess or use all the necessary equipment. A review of a typical day's work in different types of practice confirms the usual belief that minor ailments, and acute and chronic illness, provide most of the general practitioner's work—the conditions most often seen being respiratory, digestive, and circulatory disorders, rheumatic and skin diseases, children's diseases, and minor psychological disturbances. Doctors who attend current postgraduate courses complain that their lecturers do not give sufficient attention to these types of illness.

DUTIES OF THE FAMILY DOCTOR

The degree of responsibility taken by doctors for various types of case differs; thus one reported that he treated most ear, nose, throat, eye, and skin cases, referring only the most difficult to a specialist, while another wrote that he referred nearly all eye cases and skin cases to the clinics. In the estimation of the committee the responsibilities undertaken by the general practitioner include continuous care of patients, health education and preventive medicine, treatment of the patient as an individual, diagnosis, treatment (including emergency treatment, aftercare, and reablement), information to specialists, administrative and legal responsibilities, and other miscellaneous duties. As family doctor he sees the beginnings of disease and the interrelation of illness, environment, and occupation. He is able to give continuous advice on the maintenance of health, and undertakes such active preventive measures as vaccination and diphtheria immunisation. He sees the patient whole, as a person living in a particular setting exposed to strains which he is able to assess. He gives the first-aid treatment in all emergencies, and sends full information with any patient when he refers to a consultant. He has many legal and administrative duties to do with the National Health Service, death certificates, dangerous drugs, and the giving of medical evidence; and these demand from him much clerical work. In addition he may hold one or more part-time appointments—in public health, industrial work, maternity and child-welfare work, or school inspection. And finally he is always being asked for advice on subjects which are often a far cry from straight medicine.

Since, to meet these many calls, the general practitioner must have a wide range of knowledge based on the fundamental principles of medicine, and a synoptic grasp of the scope of the specialties, the committee deprecate the traditional distinction in status between general practice and the specialties. Every doctor should be free to follow the branch of medicine which appeals to him, and should be properly trained after registration for his chosen branch; and all branches should offer reasonable prospects of material reward. Opportunities should be made for general practitioner and specialist to cooperate fully. Doctors in a group practice should each be encouraged to develop some special interest; but this should be within the scope of general practice, and should not include services ordinarily given by a fully trained specialist.

The committee see the general practitioner as humane, easy with all company, ready for work which demands the sacrifice of much of his home life, healthy and robust, with cultural interests that develop the whole man in him.

THE WELL-RUN PRACTICE

In order to do his work and still have time to keep abreast of medical advances, the doctor needs to organise his work well, acquiring some understanding of business method, and the ability to delegate non-medical duties to competent ancillary staff. An account is given of a well-organised firm in a small country town: a full-time secretary and qualified dispenser are employed who "do all possible work that can be done by an unqualified person, i.e., telephones, correspondence, appointments, admission to hospital, all forms, visiting lists, all dispensing, urine testing, &c." The surgery is well designed, with dispensary, large waiting-room, and two consulting-rooms, all communicating by means of small talking-hatches as well as doors.

Yet even a well-organised practice cannot run itself while the doctor is attending a refresher course. The suggestion that a central pool of permanent locums should be provided did not commend itself to the committee, since doctors who are willing to spend their lives in this pursuit are not usually of the highest quality. Locums can best be found, the committee believe, among young doctors returning from abroad or waiting for appointments, or newly discharged from their term of National Service with the Forces. Young doctors training for general practice should be allowed, they consider, to take short locums in their third postgraduate year.

General practice today gives greater opportunities than it did for health education of the family, and carries a greater responsibility for prompt and accurate diagnosis. The doctor must have time to do his work properly—to make thorough examinations, to see his patients, and to consult specialists as often as he deems necessary—as well as time for postgraduate study. He must not be isolated from other medical services, or from his colleagues.

The First Three Years

The committee recommend that before the newly registered doctor begins independent general practice he should spend three years in specially designed training. For the first of these years he should act as trainee and assistant to an established general practitioner. The second year is to be spent in specially designed and preferably residential hospital appointments, and the third should provide supplementary training at the choice of the trainee. The whole course would be organised by a postgraduate committee and dean appointed by a university or medical school. During his three-year period the doctor would receive an adequate salary, and take an amount of responsibility appropriate to his experience. After consulting with the heads of the Forces' medical services, the committee decided to recommend that the 18 months spent in National Service should count as 12 months of the three years' training for general practice.

---

[2] [illegible] General Practitioner. London: British [illegible] 1950. Pp. 88. 7*s*. 6*d*.

The general practitioner to whom the assistant trainee is to be attached in his first year must be experienced; but the committee is not in favour of compiling an "approved list" of principals. Every practitioner who has been in independent practice for not less than five years should be allowed, if he can provide the right opportunities, to train entrants for general practice. The committee believe that a few years' experience would show which principals were the best teachers, and trainees would gravitate to them. The teacher's aim would be to show the trainee how the general practitioner lives and works, how he approaches and handles patients and relatives, and how he runs his practice. Information on the administrative side of general practice might, it is suggested, be given in a series of lectures during the intern year, and a syllabus is outlined, covering setting up in practice, common ailments, equipment, record-keeping and paper-work, preventive medicine in general practice, and medical ethics.

The hospital appointments during the second year of training should be resident posts in the larger non-teaching hospitals under the regional hospital boards, and should give the trainee experience of the kind of case met in general practice and enable him to recognise when to seek specialist help. Though arrangements should be flexible, to cater for varying tastes, each trainee should be encouraged to get experience of infectious diseases, obstetrics, pædiatrics, ear, nose, and throat conditions, eye and skin diseases, psychological medicine, and casualties. He should also acquire those techniques in treatment and pathological investigations which he will need in practice. In the third year the trainee could either take further hospital appointments, or simultaneous clinical assistantships in different subjects, and should do a short period of whole-time work in a laboratory. He should also have some further instruction in psychiatry.

Continuous Education

Postgraduate education for those in general practice is seen as a process continuing throughout active life, intended to preserve and increase technical competence and keep the doctor in touch with hospital practice and medical advances. The need for postgraduate education of general practitioners was agreed to be great, both by consultants and the general practitioners themselves. Current courses are said to be "insufficient in extent and inadequate in content."

The postgraduate committee and dean appointed by the university should be responsible, it is suggested, for coördinating arrangements for postgraduate education of general practitioners in the area, and should collaborate with hospitals, specialists, and medical committees and societies for the purpose. Courses of varying lengths should be available, but educational work in the hospitals —clinical and clinicopathological discussions and conferences, and ward rounds—should be just as important as set courses, and should supplement the activities of local medical societies.

THE WELL-PLANNED COURSE

Postgraduate courses will usually require the doctor to leave his practice for a weekend, a week, or a fortnight; and the committee consider the last, held in an appropriate teaching or regional hospital, to be the most useful. They oppose the idea of compulsory attendance, or the offer of special inducements, believing that a well-run course with good and useful teaching and social amenities—including entertainment for the doctors' wives while their husbands are attending lectures—should be its own attraction. Teachers of high standing should be selected for their interest and competence in teaching, and should include suitable general practitioners. Full use should be made of cases in the chronic wards, outpatients, and casualty departments of non-teaching hospitals. The course should refresh the doctor's basic knowledge of procedures, including clinical methods; inform him on new methods of diagnosis and treatment; relate new knowledge to his own approach to medicine and to his patients; and restate the contribution of other sciences to medicine. Methods of teaching should include tutorial classes, conferences, demonstrations, and discussions.

ALL THE YEAR ROUND

Local arrangements should also be made, for continuous postgraduate training. The local medical society, which can do much, should become a medical club, the centre of all professional life. The committee recommend that in each area the profession should develop an active medical society, in the conduct of which general practitioners and specialists should participate. Programmes should include lectures and demonstrations, courses at local hospitals, discussion groups and conferences, and [illegible] and clinicotherapeutic conferences, [illegible] ns trusts, and meetings with members of other professions. It is suggested that edited reports of clinical conferences of interest to general practitioners should often be published in a general medical journal.

The committee believe that the divorce of the general practitioner from the hospital is bad for the efficiency of the whole medical service. Arrangements should be made for doctors to attend outpatient sessions and ward rounds, and to hold clinical assistantships which would enable them to develop their knowledge of a particular aspect of general practice, and to move more easily from general practice to specialties if they wished. Some doctors, it is thought, would prefer a fortnight's resident hospital appointment as an alternative to a refresher course; and this might be arranged. The committee also strongly support, from an educational standpoint, the growing demand among family doctors for hospitals or wards where they can treat those of their own patients who cannot conveniently be nursed at home.

Self-education during practice must depend on contact between the doctor and the hospital medical staff. The doctor should accompany his patient to hospital for consultation, when possible, and should be free to visit him in the wards at any time. The hospital medical staff should keep the family doctor informed of the patient's progress while he is in hospital.

Doctors in general practice should have opportunities to contribute to field researches in medicine and social science planned by university departments. They should also have leisure for "systematic, unhurried and uninterrupted professional reading," and should make full use of medical libraries, including the facilities now offered for purchasing 'Photostat' copies of any given article at a small price.

The committee conclude that the better the general practitioner the more insistent will be his demand for adequate and appropriate postgraduate medical education. He must be given time for it, however, and on a long-term view this should be possible if general practice gains in interest and status, so that more newly qualified men are willing to enter it. The committee believe that if their recommendations are fulfilled, a larger supply of such doctors will be forthcoming.

THE PROBLEM OF CHILDREN'S DENTISTRY

W. H. LITTLEFIELD
B.D.S. Durh., H.D.D. Edin.
ASSISTANT DENTAL SURGEON, NEWCASTLE UPON TYNE DENTAL HOSPITAL

FOR many years now we have been accustomed to a system of rationing in this country. This ensures, in times of scarcity, an even distribution of materials and commodities among the whole population. We have, moreover, established priorities in foods and vitamins for mothers and children, to safeguard the health of the present and future generations. Our community rightly considers health to be a cornerstone in our social structure. Yet, paradoxically enough, in Britain today the facilities for a very important part of the child health service, namely, children's dentistry, have deteriorated so rapidly as to constitute nothing short of a major tragedy. Dental caries, one of the commonest of children's diseases, is being allowed to become rampant once again. The loss of its control is causing the greatest disquiet among members of the dental profession and this concern is reflected in numerous contributions to the dental journals and in letters from dental surgeons to the lay press. The anxiety of the profession has now spread to the parents, who are becoming increasingly aware that all is not well with the arrangements for the dental treatment of their children. In his recent article in THE LANCET MacGregor (1950) has emphasised the urgency of the problem of children's dentistry and suggested a possible solution.

This seems an appropriate time, therefore, to survey the present state of children's dentistry, to define the problem which faces us, and to indicate in which directions the solution may be found.

CHILDREN'S DENTISTRY TODAY

In Britain today children may receive dental treatment from general practitioners, from the School Dental Service, or at the teaching hospitals. Theoretically, the children are well served. Practically, we know the reverse is true. Many dental practitioners, inundated by the demands of adults, can find little opportunity for the treatment of children, which is often more trying and time-consuming. Furthermore, the disparity in fees for the conservation of deciduous and of permanent teeth in the National Health Service is no incentive to carry out comprehensive treatment for children.

The School Dental Service, after the set-back it suffered during the war years, made rapid strides towards recovery. The strength of the service, which at the beginning of 1946 was the equivalent of only 634 whole-time officers, had increased to the equivalent of 921 by the end of 1947. In England and Wales at that time only six local authorities had failed to appoint a senior dental officer. The post-war difficulties of equipment were being overcome and shortages of premises were being made good. Orthodontic schemes were being developed, and more and more children could enjoy the advantages of general anæsthesia. Greater opportunities were being offered to dental officers for postgraduate instruction. Indeed, we had a vigorous and healthy School Dental Service which was rapidly developing and was contributing most effectively to the battle against dental disease in children.

Then came July 5, 1948, and the decline of the School Dental Service began. By the end of 1948 the number of school dental officers had fallen to the whole-time equivalent of only 868. Since then there have been further depletions, until in Scotland, for instance, six counties have no school dental officer. Thus, if we estimate the practising strength of the dental profession in Britain as 12,000, less than a twelfth of the total remain to deal with children's dentistry. Yet, of the total of 50 million people in the United Kingdom, 10 million are children under the age of 15 years. So less than a twelfth of the profession is responsible for the dental care of over a fifth of the population. Admittedly, children up to the age of 3 years need little if any dental treatment, but there are many adults with full dentures who require just as little attention.

This inequable distribution of dental man-power has only one cause: the gross disparity between the earnings of dental surgeons in private practice and the salaries of the School Dental Service. One can understand the dilemma of the local authorities; if they raise the salaries of their dental officers they may have to make a general increase in the pay of comparable grades of their employees.

Meanwhile the exodus of school dental officers continues, and the collapse of the service has been disastrous. In some areas only an emergency service is now possible, and great credit is due to those who, resisting the financial attractions of private practice, have remained true to the ideals on which the provisions for children's dentistry were based.

Parents are finding difficulty in getting their children's teeth attended to by private practitioners under the N.H.S., and only a small proportion are able (and willing) to pay for their children to be seen as private patients; so the collapse of the School Dental Service has led to an inundation of the teaching hospitals. Not only is there a greater influx of orthodontic cases but more and more children are seeking general routine treatment. As a result, it has become impossible to deal with all who attend, and waiting-lists grow longer every day.

This brief survey of the facilities for the dental treatment of children in Britain today shows at least that there is no cause for complacency. The whole organisation of children's dentistry, which took so long to build, has suffered grave damage in the last few months. To repair it, or if necessary rebuild it, is a task which many of us are anxious to see undertaken. Let us, then, define more exactly the extent of the task.

THE TASK OF REPAIR

The provisions for children's dentistry divide themselves naturally into two parts: (1) general dental attention for all children; and (2) orthodontic treatment for those who need it.

In the past the largest part of the general dental attention of children has been provided by the School Dental Service. This, I believe, must still be an ideal for the future. How many dental officers are required to provide a comprehensive service for all children? The United Kingdom has about 6½ million school-children, and the Minister of Education has said that each dental officer should be responsible for the dental care of about 3000. Presumably it is not anticipated that all of these children will accept treatment and certainly a proportion will not require it. Nevertheless, on the basis of these figures, the strength of the School Dental Service must be increased to the whole-time equivalent of more than 2000 officers.

Turning next to the more intricate problem of providing for orthodontics, it must first be considered what proportion of children need this treatment. In the U.S.A., Brandhorst (1932) found that over half of the children he examined had dental irregularities, and Salzmann (1943) confirmed this. In Britain Pringle and Breakspear (1943) and Sclare (1945) have reached similar conclusions. Assuming then that about half of all the children of school age in Britain require orthodontic treatment the problem is indeed formidable. However, Brandhorst, Salzmann, and Sclare are agreed iat as many as four-fifths of the children who require rthodontic treatment have malocclusions which would spond to simple treatment or could be prevented, and nly the remaining fifth require complicated treatment. herefore it seems reasonable to suppose that, of all the chool-children in Britain, as many as 40% have simple r preventable malocclusions, and some 10% have more evere deformities. The prevention and treatment of imple malocclusions appear to come naturally within he province of the school dental officers, whereas the nore complicated ones should be treated by orthodontists.

How many orthodontists are then required to correct he severer malocclusions present in 10% of the 6½ nillion school-children? It is generally agreed that one rthodontist with a practice of 800 children can treat 200 new patients each year. On this basis the number of orthodontists required is over 3000! This, of course, is impossible, and we must resign ourselves, however reluctantly, to the inevitable conclusion that a large proportion of the malocclusion present in children today must go untreated. What then is the problem for the future? Our 6½ million school-children are between 5 and 14 years of age—in other words, their age-groups extend over ten years. Consequently the problem in the future will be to provide specialist orthodontic treatment, not for 10% of 6½ million, but for 10% of 650,000 children each year. Again assuming that one orthodontist can undertake treatment for 200 new patients each year, it follows that just over 300 orthodontists will be required.

To sum up, the first part of the task of providing for children's dentistry resolves itself into increasing the strength of the School Dental Service to the whole-time equivalent of over 2000 officers, who would be responsible for the general routine treatment of children, including simple orthodontic measures. The second part of the task involves an increase in the number of orthodontists to over 300.

POSSIBLE SOLUTIONS

An equable distribution of the dental profession, on the basis of population, would be to allot a fifth of the total to children's treatment—i.e., 2400 out of the estimated practising strength of 12,000. The School Dental Service would then become fully staffed and the control of dental disease in children would again be possible. All would agree that this is a very desirable aim. How can it be achieved? It is obvious that better surgeries and equipment, more facilities for orthodontic treatment, and greater opportunities for post-graduate instruction are welcome developments which indeed were taking place in the School Dental Service. But above all, and this urgently, there is needed a revision of salaries to compare more favourably with those in private practice. Then, and not until then, will the tide turn and the flow of dentists back into the School Dental Service begin.

Nevertheless, the present recruitment rate to the profession is insufficient to maintain its strength. So any increase in the number of school dental officers will reduce the number of dentists in private practice and will curtail the facilities for the dental care of adults, many of whom, even now, are finding it very difficult to obtain dental treatment.

To overcome these difficulties it is being suggested in some quarters that New Zealand nurses should help our numerically small School Dental Service to take care of the children. In this way the greater part of the profession would be left to treat adults. The disadvantages of such a scheme must be obvious to all. The treatment undertaken by dental nurses would be limited to the simpler types of conservation and straightforward extractions. Would they then provide an effective contribution in the fight against dental disease? Surely the answer to this question must be that any help in the treatment of children would be appreciated at this time. Unfortunately the problem is more involved.

Thus, though it may be possible to train dental nurses under the supervision of dental officers in the school clinics, a more uniform and comprehensive training would be possible in a dental school. But our present schools are working to capacity, so a new school would have to be established. In that case it should be decided whether to train dental nurses or to concentrate on training fully qualified dental surgeons.

If we postulate that a new school is to be established it would be interesting to examine the respective outputs of dental nurses and dental surgeons and then assess their contributions to children's dentistry. The training of a dental nurse takes only two years and the course for a dental surgeon is at least twice as long. Consequently we would expect a new school to train at least twice as many nurses as fully qualified dentists. What then would be their respective contributions to the dental treatment of children? One school dental officer is expected to undertake the care of 3000 children. However, the report of the Chief Medical Officer of the Ministry of Education (1949), shows that only 80% of children require treatment, and Wynne (1948) estimated the crude acceptance-rate as 72%. This means that of 3000 children only 1700 would both require and accept treatment. On the other hand, Owen (1949) states that each New Zealand nurse could deal with 500 children. On the basis of these figures, one British school dental officer could carry out full treatment for more than three times the number of children for whom one New Zealand nurse could perform only simple conservative measures and extractions. Nevertheless the caries rate is thought to be greater in New Zealand than in Britain, and, if the geographical problem there is more complicated, it is possible that a New Zealand nurse, working in Britain, could treat more than 500.

To sum up, to decide whether to train dental nurses or dental surgeons, we must strike a balance between two conclusions. It appears that, with the same facilities, it is possible to train more nurses than surgeons. On the other hand, fully qualified dentists would provide a more effective contribution than dental nurses to the treatment of children. Let us then await the observations of the delegation which is examining the New Zealand scheme, remembering the various factors involved.

We have seen that to provide for orthodontic treatment over 300 orthodontists will be required. Where are these to be trained? In this country there are a variety of orthodontic philosophies and methods of treatment. To preserve this healthy breadth of thought and wide conception it is expedient that orthodontists should be trained in the various teaching hospitals and schools throughout Britain.

Thus the newly-qualified dentist who aspired to be an orthodontic specialist would, as the first step in his career, obtain the post of house-surgeon in one of our teaching hospitals. After holding this post for a year he would carry out the inevitable period of National Service and then return to the teaching hospital as a registrar. During these first years of his professional career he would acquire a deeper knowledge and a wider experience of the various branches of dentistry, and, in addition, would be studying for a higher qualification. At this stage he might well benefit by spending six months or so doing the routine dental treatment of children in the School Dental Service. In this way he would gain experience in the treatment and handling of children. At the same time he would become conversant with the everyday problems the school dental officer has to face and this would make for better coöperation and mutual understanding in the future.

On this broad basis of professional education and experience he would then be in a position to erect his specialty of orthodontics. To achieve this he would obtain the post of senior registrar in the orthodontic department of a teaching hospital. His instruction would be by means of lectures in the dental school and the treatment of patients in the hospital. He should be given opportunities to learn the construction of the various types of appliances he uses and also for research. He might also spend time in the children's department of a nearby general hospital and so gain a wider and more practical knowledge of children's diseases. Lastly, to develop as broad an outlook as possible, he might undertake a full-time postgraduate course in orthodontics for six or twelve months in some other teaching hospital or school. At the end of this period, he would be eligible for a special diploma.

After such a comprehensive and thorough education the orthodontist would be ready to practise his specialty, fully equipped to play his part in the treatment of the dental irregularities of the future generation.

* * *

These then are the directions in which the solution to the problem of children's dentistry may be found. The decisions we must make and the task of carrying them into effect will be by no means easy. But the problem is urgent, not only for the welfare of the profession, but also for the good of the children and the health of the nation in years to come. Let us seek the answer deliberately and conscientiously, remembering that the plans we make for the future will be judged by the children whose treatment is being neglected today.

DEATH OF A MIND

A STUDY IN DISINTEGRATION

I FIRST remember my father as a well-built, active man with a wide range of interests. His work required both intellectual and practical ability, and those who could judge his achievement spoke highly of it. I was more impressed at the time by the happy enthusiasm with which he would turn from weightier matters to entertain his small daughter. In 1924, at the age of 49, he retired to the country to devote himself to scientific research of a more academic kind. Possibly the stress of his previous work had begun to tell on him, and this may have influenced his decision, but there was no outward sign that his powers might be failing. Over the next few years he built up a reputation which brought him into contact with fellow workers in many parts of the world. Unlike his earlier work, which required advanced mathematics, what he was doing now came within my own mental range, and I helped him for two years as a prelude to my university studies.

Over the period that we worked together, sometime in the early 1930s, I became gradually aware that the fine edge of his intellect was becoming dulled. He was less clear in discussion and less quick to make the jump from a new piece of evidence to its possible significance. He spent more time over his work and achieved less; and he found it increasingly difficult to get his results ready for publication. He tended also to become portentous and solemn about his subject, as though one small corner of knowledge nearly filled his world, and the wider horizons were narrowing in. The change was so slow as to be barely perceptible, and the signs vanished when I tried to pin them down: they were like those faint stars which are seen more easily when they are not in the direct line of vision. I was left with a feeling of uneasiness which I could not justify.

In 1935, after a period of absence, I looked forward with especial pleasure to my home-coming, but when we met I knew, with immediate certainty that I had lost the companion of my earlier years. The change was as yet mainly a loss of intellectual clarity and he remained himself, but a self that was subtly devitalised. To me it was as though a light had gone out, but no-one else seemed to notice anything amiss. Somewhere between a year and eighteen months later I happened to be at home and we were doing some carpentry about the house. We paused to consider a problem which had thwarted us, and I hit on a solution and outlined the idea. My father could not grasp the principle of it until I gave a demonstration, and even then he lacked sufficient manual dexterity to carry it out. I was profoundly shocked by this, for it was the first clear-cut objective evidence I had of the downhill change which was taking place. It reflected on a practical level precisely the same failure of integration and coördination which I had noticed already on the intellectual plane. His ability was still well within normal limits; but I knew what it had been, and the difference was startling.

By this time he was worried about his general health and attended a doctor from time to time with rather vague symptoms. For several years he had been said to have low blood-pressure, but nothing was found wrong apart from this, and he was reassured. As time went on his physical condition got worse; his walking and his speech were obviously affected, but it was not until the bank failed to recognise his signature on a cheque that I was able to persuade him to ask for specialist advice. In 1937 he was diagnosed as having Parkinson's disease, and the classical physical signs were by then well marked. His mental ability had deteriorated further, though it still passed as normal to anyone who did not know him well. He tried to carry on with his work, but he did not make any headway and became more and more depressed about it. His character remained essentially the same except that he could no longer endure unorthodox views. His own moral standards and religious beliefs were simple and sincere and so firmly grounded that he had found it easy to be patient and tolerant with those who could not accept them. Now, however, if he chanced to overhear one of the eager iconoclastic arguments of youth he became disturbed and petulant and it seemed as though his mental organisation had become less secure even at its deeper levels.

* * *

In the spring of 1938 an attack of pneumonia would have ended the story, but for the recent introduction of sulphonamides. During this illness he was troubled one day by a brief hallucination. The rooks flying across the field appeared as a procession of people or something of the sort; nothing dramatic, but he worried about it afterwards. He was encouraged to dismiss the matter as a chance result of the febrile illness, and he would have done so if he had not found later that the same thing in a milder form began to happen frequently. It appeared to him as a new and alarming symptom, but I think it was the further stage of a process which had been going on for some time. Both sight and hearing were involved, but the effect on hearing was more easily observed by others, while the disturbance of vision—once his attention had been drawn to it—was most noticeable to him.

For the past year or more it had been assumed that was going deaf; but, as far as I could discover, his aring was still acute. The trouble was that he failed to cognise the sounds he heard. You might say something e " the postman hasn't come " and he would hear it as the grocer's cut his thumb." It was superficially like hat might happen with someone who had grown par- ally deaf, but closer attention showed up the difference.

It is easiest to describe the breakdown by comparison th the normal. We may hear a phrase moderately early and yet not get it right at once. I suppose what appens is that the brain first registers a sound pattern nd then compares it with previously remembered atterns so that the gaps can be filled in and the words entified. The result seems to be checked at a higher mental level to see if it " makes sense " before it is fully ccepted as having been heard. When we hear something mprobable we are sometimes conscious of the check and closer scrutiny which take place quite automatically. expect all of us can remember instances when our mind discarded its first attempt to complete a puzzle and held on to the remembered sound until it turned up something else which fitted better. A second choice which makes better sense may match the sound more accurately as well, and we will perhaps conclude with confidence that we " heard " that in the first instance. In a deaf person the disability is presumably at the first stage. The sensory information is scanty or distorted, there are many gaps to be filled, and identification of the words is much more difficult. Allowing for that handicap the next stage—unless there are senile changes also—is carried out in the usual way. In my father's case it was at this second stage that the most gross defect was seen.

The same principle evidently applies to other forms of sense perception, and it was a description of the subjective effects in the visual field that showed me what was happening. If my father glanced at a dark shape which was rather like a black cat he did not instinctively look again to make sure what it was; he *simply saw* a cat. His mind fitted the sensory impression to the first rough approximation which suggested itself, and accepted it without further question, however unlikely it might be in the context. I had not realised until then that the critical sifting process which is only rarely brought to our notice must be going on all the time in normal perception, and that when it fails the result is most confusing to the conscious mind. My father discussed the problem with me in some detail, as he was naturally disturbed to find that he kept on seeing things which were not there. He did not feel it was much use talking to the doctors about it. He was, I think, deterred from taking them further into his confidence after his first suggestion that his mind was affected had been rather lightly dismissed. I could not interfere in that direction, so I did the best I could by the light of nature. When we got down to it together and considered the evidence it seemed clear that he was not hallucinated in the sense of seeing things which were a projection of some idea in his mind. The things he saw always had some basis in actuality, but his brain was constantly sending on messages which had, so to speak, been badly decoded. When he began to understand that this was a mechanical defect he found it much less alarming, and he learnt to allow for it to a considerable extent. The domestic misunderstandings which resulted from it became more comprehensible, and he had sufficient confidence in me to accept my assurance that he was quite sane. No-one else had any suspicion of his difficulties, and I naturally respected his confidence. Since nothing could be done about the condition it would only have caused added distress to others if they had known, and an anxious atmosphere around him always aggravated his condition.

* * *

That was the situation in the autumn of 1938, and the suggestion that he should then go for a trip abroad put me in a difficult position. He felt convinced that it would do him good, and his medical advisers encouraged this belief. I think their view was that it would do him no harm, and that a change of scene would relieve his depression. This was, on the face of it, reasonable enough; but when I considered the international situation and my father's mental state I could not help feeling apprehensive. I had no opportunity of seeing the doctors myself though I was able to ensure that the question of mental fitness was raised. The verdict—as related to me at second hand—was that this disease did not affect the mind and his mind therefore could not be affected. There seemed nothing more that I could do. After all, even if I had insisted on saying what I knew, I had by then no hope that anyone would believe me. My sense of isolation was such that I wondered from time to time whether I was *imagining things* and whether it was in fact my own mind that was giving way. I weighed it up and decided to reserve judgment until events had proved which side was right. I did nothing further to oppose the plan, but I felt I could not take the responsibility of letting my parents go alone. I made arrangements to interrupt my studies, and we left England at the end of the year.

* * *

Our destination was an isolated resort in mountainous country about fifteen miles from the nearest small town. The sea voyage and further train journey passed without incident, and my father was cheered to return to a place which he had known in years gone by and which had happy associations for him. It was soon evident, however, that unfamiliar faces and a foreign language were putting too heavy a strain on his failing faculties. At home among people whom he had known for years and could recognise easily he had been confident that he was among friends, and if he sometimes thought they said *strange or disturbing things* the misunderstandings could generally be put right. Now, listening every day to a background of foreign conversation which, even when fit, he could not easily have followed, he was soon bewildered. His mind accepted the nearest English equivalent to the sounds he heard, and the task of keeping in touch with reality against such odds became impossible. Hearing what he thought was English spoken, he addressed other hotel residents in his own language, to be met by uncomprehending stares. He naturally came to feel that they were hostile to him, and he began gradually to make order out of his mental chaos by systematising, in a delusional way, what he heard and saw. The dining-hall became for him the scene of an interminable lawsuit, and I had often to provide some diversion to prevent him from standing up to give evidence between the courses. At this stage my mother could not have failed to realise what was happening were it not that his speech was so blurred as to be almost unintelligible.

He was still potentially rational. His delusions were not determined by a warped mental outlook, but were a reasonable attempt to make sense out of what was subjectively a hopelessly confusing situation. In days gone by I had learnt to follow his train of thought intuitively, and I could still keep close to him in spite of his difficulty with speech. I found that if I got him away from other people and steered his mind to topics which he had handled with ease in the past he became rational quite quickly. I sometimes led him into long and interesting discussions on subjects which he knew and cared about, and when he got the sense of being on familiar ground, where he could still tread firmly, the black cloud of depression lifted and he became his old self. As soon as he returned to the strain of new and unfamiliar situations he relapsed. It was well on into February has to face and this would make for better coöperation and mutual understanding in the future.

On this broad basis of professional education and experience he would then be in a position to erect his specialty of orthodontics. To achieve this he would obtain the post of senior registrar in the orthodontic department of a teaching hospital. His instruction would be by means of lectures in the dental school and the treatment of patients in the hospital. He should be given opportunities to learn the construction of the various types of appliances he uses and also for research. He might also spend time in the children's department of a nearby general hospital and so gain a wider and more practical knowledge of children's diseases. Lastly, to develop as broad an outlook as possible, he might undertake a full-time postgraduate course in orthodontics for six or twelve months in some other teaching hospital or school. At the end of this period, he would be eligible for a special diploma.

After such a comprehensive and thorough education the orthodontist would be ready to practise his specialty, fully equipped to play his part in the treatment of the dental irregularities of the future generation.

* * *

These then are the directions in which the solution to the problem of children's dentistry may be found. The decisions we must make and the task of carrying them into effect will be by no means easy. But the problem is urgent, not only for the welfare of the profession, but also for the good of the children and the health of the nation in years to come. Let us seek the answer deliberately and conscientiously, remembering that the plans we make for the future will be judged by the children whose treatment is being neglected today.

In 1937 he was diagnosed as having Parkinson's disease, and the classical physical signs were by then well marked. His mental ability had deteriorated further, though it still passed as normal to anyone who did not know him well. He tried to carry on with his work, but he did not make any headway and became more and more depressed about it. His character remained essentially the same except that he could no longer endure unorthodox views. His own moral standards and religious beliefs were simple and sincere and so firmly grounded that he had found it easy to be patient and tolerant with those who could not accept them. Now, however, if he chanced to overhear one of the eager iconoclastic arguments of youth he became disturbed and petulant and it seemed as though his mental organisation had become less secure even at its deeper levels.

* * *

In the spring of 1938 an attack of pneumonia would have ended the story, but for the recent introduction of sulphonamides. During this illness he was troubled one day by a brief hallucination. The rooks flying across the field appeared as a procession of people or something of the sort; nothing dramatic, but he worried about it afterwards. He was encouraged to dismiss the matter as a chance result of the febrile illness, and he would have done so if he had not found later that the same thing in a milder form began to happen frequently. It appeared to him as a new and alarming symptom, but I think it was the further stage of a process which had been going on for some time. Both sight and hearing were involved, but the effect on hearing was more easily observed by others, while the disturbance of vision—once his attention had been drawn to it—was most noticeable to him.

which may be aroused is based on fear of the unknown and a misunderstanding of what happens to people after they have been cut off from reality in this way.

It is clear that a disease process can affect personality, and the instance I have described does no more than illustrate something which is well known. It has been suggested, and indeed it seems at first sight rather obvious, that if damage to certain areas of the brain affects character, character itself must depend upon these structures. This is, I suspect, no more than a half-truth, and because a part of it is demonstrably true it may be all the more misleading. It is reasonable to assume that a man's physical constitution is the machine through which his personality is developed and operated, but the person as a whole is something more than the sum of his parts, and personality in action behaves like a total field of force. If outward behaviour has been a camouflage for inner tension, and if a person's standards have been imposed from without and not accepted as fully worth while in themselves, even slight damage to the machine may have dramatic results; but a balanced and integrated character cannot easily be destroyed.

When my father became violently insane he was certainly not his normal self, but if one makes allowances for the confused view of reality which was relayed to him his actions were consistent and quite in keeping with his character. He had previously become so weighed down by discouragement and weakness that only an intense emotional stimulus could have roused him. The threat to his country and his family struck deeper than any fancied insults or injustice to himself, and he responded with everything he had. By what was in the circumstances an astonishing integrative effort he achieved both mental concentration and physical coordination, and if the results bore no useful relation to the facts that was scarcely to be wondered at. When it seemed to him that his country's interest and his affection for me were in conflict, he put his country first, just as he would undoubtedly have done in real life; but, although his moral judgment condemned me, he made an effort to forgive me personally for the wrongs which he believed that I had done. Although I could not know it at the time, I think his resolution not to attack me, when once made, was final. He might resist, but he would not deliberately harm me.

In acting like this my father was to a large extent following character patterns which had been established many years before; but his self was more than an automaton running along old tracks—it remained vital and capable of new adjustments even in the midst of wreckage. Towards the end of the acute stage of his illness he developed some extremely troublesome delusions about my mother's health. These caused so much distress all round that I spent a long morning trying by every means I knew to win back his confidence. In the end I was successful and for one short space he returned to complete lucidity. In that moment he knew for certain that he was losing his mind, and I think he knew as well as I did that he was losing it for ever. He faced the knowledge without flinching, and he looked beyond it at what was for him the hardest truth of all. The time had come when he must finally commit to others, who might well prove less patient and considerate than he had been, the welfare of the wife he loved. Nothing could have cost more to a man whose chief defect of character had always been a tendency to carry his protective rôle too far. He made the readjustment perfectly, and he was perhaps more truly himself at that moment than he had ever been. It was an act of will which might well command admiration in a man whose mental faculties were unimpaired, and yet it was achieved by one whose brain and nervous system were tottering on the brink of final ruin. It was, I think, a victory which secured release, for he subsided afterwards into a quiet dementia which was like a rambling dream; vivid consciousness and depth of feeling were no longer present, and I never felt another pang on his behalf.

* * *

I do not wish to draw elaborate conclusions from a single incident; I merely set it on record for consideration. Mind and body are inseparable, so far as we can tell, but experience suggests that they are no more than tools, and of much less account than the spirit whose purposes they serve.

Parliament

The Medical Bill

IN the House of Lords on May 16, when this Bill was considered on report, Lord SHEPHERD moved an amendment to clause 14 to provide that at any hearing of a case at least one of the members of the disciplinary committee who were neither registered medical practitioners nor the holders of qualifying diplomas should be eligible to attend. The amendment was agreed to.

On clause 21 he explained that it was proposed that the visitors to London schools and examinations should by agreement be appointed to act both as external inspectors on behalf of the University of London and as visitors for the General Medical Council, so that two separate inspections could be avoided. He then moved an amendment to permit recourse to the Privy Council, if ever the two bodies could not reach agreement, the Privy Council asking that directions might be given as to the procedure to be followed.

The amendment was agreed to.

The report stage of the Bill was concluded.

QUESTION TIME

Mental Disability and Divorce

Dr. CHARLES HILL asked the Minister of Health whether he was aware that no relief was afforded by the Matrimonial Causes Act, 1937, to a person whose wife or husband, having been a certified patient in a mental hospital, after an interval subsequently became a voluntary patient and was incurably of unsound mind; and whether he would introduce amending legislation so as to make available facilities for the release from the matrimonial yoke of a spouse who was incapable of enjoying normal matrimonial life through mental disability of the other spouse.—Sir HARTLEY SHAWCROSS, the Attorney-General, replied: The Matrimonial Causes Act, 1937, enables a petition for divorce to be presented on the ground that the respondent is incurably of unsound mind and has been continuously under care and treatment for at least 5 years immediately preceding the presentation of the petition. For this purpose, a person is deemed to be under care and treatment while he is detained in pursuance of an order made under the Lunacy Acts (or under the corresponding legislation in force in Scotland, Northern Ireland, the Isle of Man, or the Channel Islands) or while he is receiving treatment as a voluntary patient, being treatment which follows without any interval the period of detention already mentioned. If any interval occurs between the ending of the period of detention and the subsequent voluntary treatment it would normally relate to a period during which the patient was not regarded as insane and it would not I think be in the public interest to amend the law so as to permit a period of treatment as a voluntary patient to be taken into account in such circumstances.

Bronchial Carcinoma

In answer to a question, Mr. ANEURIN BEVAN stated that deaths registered in England and Wales classified to carcinoma of the bronchus numbered 1548 in 1940, 2839 in 1944 and 5198 in 1948.

Iodisation of Salt

Dr. BARNETT STROSS asked the Minister of Food whether he would give an assurance that salt free from iodisation would always be available for purchase by those who feared that a very small iodine content might affect them adversely.—Mr. MAURICE WEBB replied: As the trace of iodine will be very small the Medical Research Council think that adverse effects will be most unlikely; but my Food Standards Committee will bear this point in mind when considering representations about the proposed changes.

before his condition became really grave, and our return passage was booked for March. There was no possibility of getting home earlier, and I hoped that I might be able to stave off disaster meanwhile. I think I might just possibly have been successful if it had not been for the international situation.

* * *

My father had never had a good ear for foreign languages, but he could follow them on paper, and to some extent this faculty remained. When Hitler marched into Czechoslovakia the repercussions spread even to the part of the world where we were staying, and the local papers were blazoned with headlines which implied the imminence of war. This was too much. Faced with a threat which involved his own country and all that was dear to him, my father let go his last faint hold on reason and threw himself into action. The results were spectacular. Until then he had walked unsteadily with shuffling gait, his head drooped forward, his features flaccid, and when he spoke he gave confused and indistinct expression to his rambling thoughts. Now he stood straight with lifted head, strode with firm step, spoke clearly, and set out with rampant anger to find and destroy the enemy in our midst. He spent the day chasing non-existent spies in other people's bedrooms; while I chased after, explaining to the agitated guests and taking what steps I could to deal with the emergency. The hotel manager, the only responsible man about the place, had left that morning for a destination fifty miles away. I managed to telephone a message to the doctor in the nearest town, but it was some hours before he arrived. As was natural in the circumstances, my father's violence became directed against me. I was, after all, the person whom he had relied on most in his difficulties, and now that the situation forced me to restrain him it seemed to him that I, of all people, had gone over to the enemy. In that moment of despair and disillusion the full force of his love for me was turned to bitter hatred. I could understand, but I could not relieve his plight. When the crisis came we were alone in an upstairs gallery, and he turned on me with murder in his eyes. A day earlier the physical advantage would have been on my side, but mania had mobilised his last reserves of strength and he was for the time being a powerful man. My prospects of escape seemed small in any case; so, taking a chance on it, I faced him quietly with an appearance of calmness which assuredly I did not feel. For a moment the issue hung in the balance, but my confidence just turned the scale. I think if I had retreated or resisted he would probably have strangled me, but when my glance met his he could not bring himself to do it. He relaxed at last with a gesture of sad acquiescence and let himself be quietly led away. I was as much astonished by my own intuitive action as I was by the result.

The foreign doctor came and went again, leaving a sedative which was unfortunately a proprietary brand with the contents printed outside the container. My father feared we were intent on drugging him for some nefarious purpose, and he would not touch it. He had, however, recognised the doctor for what he was, and the visit sobered him a little. Even that much relief was something to be thankful for, but it was clear that no further professional help would be forthcoming. The next few days were very difficult. Quite apart from the fact that my father had charge of all our money, I expected that he might become homicidal again at any moment. I found, however, that my influence still counted for something even when he was inaccessible to reason. I was often able by manner and gesture rather than by words to make him feel that I still cared about him and that the dangers around us did not trouble me. This gave him just enough confidence to quieten him for a time, but the task would scarcely be completed before it had to be begun again. It was keeping a constantly skidding car from crashing off road.

I only went on coping because I had to, but it is surprising what an ordinary person can do under the spur of necessity. I didn't even know how frightened I was until the prospect of relief arrived. Towards the end of the week, among a group of passing visitors, I recognised a doctor from another part of the country who had treated me when I was a child. At sight of a familiar and reassuring face I had to sit down suddenly because my knees became unsteady. I explained what was happening, but he only said: "My poor, dear girl, how terribly distressing for you!" and drove away again. Sympathy can be a dangerous drug when it is not backed by practical assistance; I came nearer to losing my grip then than at any other time.

* * *

We got home in the end. All the able-bodied men were being called up by the time we left, and there were rumours that a section of the railway line had been swept away by floods. The prospect was not encouraging, but things seldom turn out as one expects and we had no serious trouble. The wave of violence had exhausted my father's constitution, and his last show of physical strength was paid for in still greater weakness and disintegration. His strength of purpose, briefly reawakened had faded too. He was childish and sometimes deliberately mischievous, but he was never dangerous again.

Once we got back to England he was admitted to a mental hospital without delay. He had long since given up the struggle of trying to relate his ideas to reality, and had retired into a private world of unimpeded action. When last I saw him he had been put in charge of running the war after Dunkirk and was well pleased with the results. He went downhill steadily. Among other physical complications he developed diabetes and he died in coma about eighteen months after admission. The post mortem showed gross physical damage to the brain, and it was apparently regarded as quite spectacular. The medical records were lost during the war, but so far as I know the findings were consistent with a severe post-encephalitic lesion.

* * *

I am not qualified to comment on the medical aspects of this story, and the last thing I wish to do is to disparage the physicians who were concerned in it. I happened to be in a position to see certain aspects more clearly, but I had not the wit to grasp why it was that things which were obvious to me might be invisible to others. In this case neither specialised knowledge of the disease nor intimate knowledge of the patient were by themselves effective. Had they been brought closer together it might have been a help both to those who were reponsible for giving advice and to those who had the task of practical management. How easy it is to be wise after the event.

The point which I would like to make myself is a different one. An illness of this kind affects others besides those who suffer from it, and the idea that a loved person—or oneself for that matter—might be transformed into something alien is disquieting. Pain and incapacity and disfigurement can be faced with fortitude, but the sight of a disease which seems to rot the self is hard to bear. It's not much use countering this with philosophical arguments, because they tend to evaporate in real-life situations, but my practical experience has reassured me about an aspect of the problem which sometimes looks more troubling that it turns out to be. There can be no shame in feeling uneasiness about it, and those who have the task of reassuring others sometimes feel the more because they must not admit to doing so; but I think some of the dread hich may be aroused is based on fear of the unknown nd a misunderstanding of what happens to people fter they have been cut off from reality in this way.

It is clear that a disease process can affect personality, nd the *instance I have described does no more than* lustrate something which is well known. It has een suggested, and indeed it seems at first sight rather bvious, that if damage to certain areas of the brain ffects character, character itself must depend upon hese structures. This is, I suspect, no more than a half-truth, and because a part of it is demonstrably true it may be all the more misleading. It is reasonable to assume that a man's physical constitution is the machine through which his personality is developed and operated, but the person as a whole is something more than the sum of his parts, and personality in action behaves like a total field of force. If outward behaviour has been a camouflage for inner tension, and if a person's standards have been imposed from without and not accepted as fully worth while in themselves, even slight damage to the machine may have dramatic results; but a balanced and integrated character cannot easily be destroyed.

When my father became violently insane he was certainly not his normal self, but if one makes allowances for the confused view of reality which was relayed to him his actions were consistent and quite in keeping with his character. He had previously become so weighed down by discouragement and weakness that only an intense emotional stimulus could have roused him. The threat to his country and his family struck deeper than any fancied insults or injustice to himself, and he responded with everything he had. By what was in the circumstances an *astonishing integrative effort* he achieved both mental concentration and physical coordination, and if the results bore no useful relation to the facts that was scarcely to be wondered at. When it seemed to him that his country's interest and his affection for me were in conflict, he put his country first, just as he would undoubtedly have done in real life; but, although his moral judgment condemned me, he made an effort to forgive me personally for the wrongs which he believed that I had done. Although I could not know it at the time, I think his resolution not to attack me, when once made, was final. He might resist, but he would not deliberately harm me.

In acting like this my father was to a large extent following character patterns which had been established many *years before; but his self was more than an* automaton running along old tracks—it remained vital and capable of new adjustments even in the midst of wreckage. Towards the end of the acute stage of his illness he developed some extremely troublesome delusions about my mother's health. These caused so much distress all round that I spent a long morning trying by every means I knew to win back his confidence. In the end I was successful and for one short space he returned to complete lucidity. In that moment he knew for certain that he was losing his mind, and I think he knew as well as I did that he was losing it for ever. He faced the knowledge without flinching, and he looked beyond it at what was for him the hardest truth of all. The time had come when he must finally commit to others, who might well prove less patient and considerate than he had been, the welfare of the wife he loved. Nothing could have cost more to a man whose chief defect of character had always been a tendency to carry his protective rôle too far. He made the *readjustment perfectly, and* he was perhaps more truly himself at that moment than he had ever been. It was an act of will which might well command admiration in a man whose *mental faculties were unimpaired*, and yet it was achieved by one whose brain and nervous system were tottering on the brink of final ruin. It was, I think, a victory which secured release, *for he subsided* afterwards into a quiet dementia which was like a rambling dream; vivid consciousness and depth of feeling were no longer present, and I never felt another pang on his behalf.

* * *

I do not wish to draw elaborate conclusions from a single incident; I merely set it on record for consideration. Mind and body are inseparable, so far as we can tell, but experience suggests that they are no more than tools, and of much less account than the spirit whose purposes they serve.

Parliament

The Medical Bill

In the House of Lords on May 16, when this Bill was considered on report, Lord **Shepherd** moved an amendment to clause 14 to provide that at any hearing of a case at least one of the members of the disciplinary committee who were neither registered medical practitioners nor the holders of qualifying diplomas should be eligible to attend. The amendment was agreed to.

On clause 21 he explained that it was proposed that the visitors to London schools and examinations should by agreement be appointed to act both as external inspectors on behalf of the University of London and as visitors for the General Medical Council, so that two separate inspections could be avoided. He then moved an amendment to permit recourse to the Privy Council, if ever the two bodies could not reach agreement, the Privy Council asking that directions might be given as to the procedure to be followed.

The amendment was agreed to.

The report stage of the Bill was concluded.

QUESTION TIME

Mental Disability and Divorce

Dr. **Charles Hill** asked the Minister of Health whether he was aware that *no relief* was afforded by the Matrimonial Causes Act, 1937, to a person whose wife or husband, having been a certified patient in a mental hospital, after an interval subsequently became a voluntary patient and was incurably of unsound mind; and whether he would introduce amending legislation so as to make available facilities for the release from the matrimonial yoke of a spouse who was incapable of enjoying normal matrimonial life through mental disability of the other spouse.—Sir **Hartley Shawcross**, the Attorney-General, replied: The Matrimonial Causes Act, 1937, enables a petition for divorce to be presented on the ground that the respondent is incurably of unsound mind and has been continuously under care and treatment for at least 5 years *immediately preceding the presentation* of the petition. For this purpose, a person is deemed to be under care and treatment while he is detained in pursuance of an order made under the Lunacy Acts (or under the corresponding legislation in force in Scotland, Northern Ireland, the Isle *of Man*, or the Channel Islands) or while he is receiving treatment as a voluntary patient, being treatment which follows without any interval the period of detention already mentioned. If any interval occurs between the ending of the period of detention and the subsequent voluntary treatment it would normally relate to a period during which the patient was not regarded as insane and it would not I think be in the public interest to amend the law so as to permit a period of treatment as a voluntary patient to be taken into account in such circumstances.

Bronchial Carcinoma

In answer to a question, Mr. **Aneurin Bevan** stated that deaths registered in England and Wales classified to carcinoma of the bronchus numbered 1548 in 1940, 2839 in 1944 and 5198 in 1948.

Iodisation of Salt

Dr. **Barnett Stross** asked the Minister of Food whether he would give an assurance that salt free from iodisation would always be available for purchase by those who feared that a very small iodine content might affect them adversely.—Mr. **Maurice Webb** *replied*: As the trace of iodine will be very small the Medical Research Council think that adverse effects will be most unlikely; but my Food Standards Committee will bear this point in mind when considering representations about the proposed changes.

before his condition became really grave, and our return passage was booked for March. There was no possibility of getting home earlier, and I hoped that I might be able to stave off disaster meanwhile. I think I might just possibly have been successful if it had not been for the international situation.

* * *

My father had never had a good ear for foreign languages, but he could follow them on paper, and to some extent this faculty remained. When Hitler marched into Czechoslovakia the repercussions spread even to the part of the world where we were staying, and the local papers were blazoned with headlines which implied the imminence of war. This was too much. Faced with a threat which involved his own country and all that was dear to him, my father let go his last faint hold on reason and threw himself into action. The results were spectacular. Until then he had walked unsteadily with shuffling gait, his head drooped forward, his features flaccid, and when he spoke he gave confused and indistinct expression to his rambling thoughts. Now he stood straight with lifted head, strode with firm step, spoke clearly, and set out with rampant anger to find and destroy the enemy in our midst. He spent the day chasing non-existent spies in other people's bedrooms; while I chased after, explaining to the agitated guests and taking what steps I could to deal with the emergency. The hotel manager, the only responsible man about the place, had left that morning for a destination fifty miles away. I managed to telephone a message to the doctor in the nearest town, but it was some hours before he arrived. As was natural in the circumstances, my father's violence became directed against me. I was, after all, the person whom he had relied on most in his difficulties, and now that the situation forced me to restrain him it seemed to him that I, of all people, had gone over to the enemy. In that moment of despair and disillusion the full force of his love for me was turned to bitter hatred. I could understand, but I could not relieve his plight. When the crisis came we were alone in an upstairs gallery, and he turned on me with murder in his eyes. A day earlier the physical advantage would have been on my side, but mania had mobilised his last reserves of strength and he was for the time being a powerful man. My prospects of escape seemed small in any case; so, taking a chance on it, I faced him quietly with an appearance of calmness which assuredly I did not feel. For a moment the issue hung in the balance, but my confidence just turned the scale. I think if I had retreated or resisted he would probably have strangled me, but when my glance met his he could not bring himself to do it. He relaxed at last with a gesture of sad acquiescence and let himself be quietly led away. I was as much astonished by my own intuitive action as I was by the result.

The foreign doctor came and went again, leaving a sedative which was unfortunately a proprietary brand with the contents printed outside the container. My father feared we were intent on drugging him for some nefarious purpose, and he would not touch it. He had, however, recognised the doctor for what he was, and the visit sobered him a little. Even that much relief was something to be thankful for, but it was clear that no further professional help would be forthcoming. The next few days were very difficult. Quite apart from the fact that my father had charge of all our money, I expected that he might become homicidal again at any moment. I found, however, that my influence still counted for something even when he was inaccessible to reason. I was often able by manner and gesture rather than by words to make him feel that I still cared about him and that the dangers around us did not trouble me. This gave him just enough confidence to quieten him for a time, but the task would scarcely be completed before it had to be begun again. It was keeping a constantly skidding car from crashing off road.

I only went on coping because I had to, but it is surprising what an ordinary person can do under the spur of necessity. I didn't even know how frightened I was until the prospect of relief arrived. Towards the end of the week, among a group of passing visitors, I recognised a doctor from another part of the country who had treated me when I was a child. I do not wish to draw elaborate conclusions from a single incident; I merely set it on record for consideration. Mind and body are inseparable, so far as we can tell, but experience suggests that they are no more than tools, and of much less account than the spirit whose purposes they serve.

Parliament

The Medical Bill

In the House of Lords on May 16, when this Bill was considered on report, Lord SHEPHERD moved an amendment to clause 14 to provide that at any hearing of a case at least one of the members of the disciplinary committee who were neither registered medical practitioners nor the holders of qualifying diplomas should be eligible to attend. The amendment was agreed to.

On clause 21 he explained that it was proposed that the visitors to London schools and examinations should by agreement be appointed to act both as external inspectors on behalf of the University of London and as visitors for the General Medical Council, so that two separate inspections could be avoided. He then moved an amendment to permit recourse to the Privy Council, if ever the two bodies could not reach agreement, the Privy Council asking that directions might be given as to the procedure to be followed.

The amendment was agreed to.

The report stage of the Bill was concluded.

QUESTION TIME

Mental Disability and Divorce

Dr. CHARLES HILL asked the Minister of Health whether he was aware that no relief was afforded by the Matrimonial Causes Act, 1937, to a person whose wife or husband, having been a certified patient in a mental hospital, after an interval subsequently became a voluntary patient and was incurably of unsound mind; and whether he would introduce amending legislation so as to make available facilities for the release from the matrimonial yoke of a spouse who was incapable of enjoying normal matrimonial life through mental disability of the other spouse.—Sir HARTLEY SHAWCROSS, the Attorney-General, replied: The Matrimonial Causes Act, 1937, enables a petition for divorce to be presented on the ground that the respondent is incurably of unsound mind and has been continuously under care and treatment for at least 5 years immediately preceding the presentation of the petition. For this purpose, a person is deemed to be under care and treatment while he is detained in pursuance of an order made under the Lunacy Acts (or under the corresponding legislation in force in Scotland, Northern Ireland, the Isle of Man, or the Channel Islands) or while he is receiving treatment as a voluntary patient, being treatment which follows without any interval the period of detention already mentioned. If any interval occurs between the ending of the period of detention and the subsequent voluntary treatment it would normally relate to a period during which the patient was not regarded as insane and it would not I think be in the public interest to amend the law so as to permit a period of treatment as a voluntary patient to be taken into account in such circumstances.

Bronchial Carcinoma

In answer to a question, Mr. ANEURIN BEVAN stated that deaths registered in England and Wales classified to carcinoma of the bronchus numbered 1548 in 1940, 2839 in 1944 and 5198 in 1948.

Iodisation of Salt

Dr. BARNETT STROSS asked the Minister of Food whether he would give an assurance that salt free from iodisation would always be available for purchase by those who feared that a very small iodine content might affect them adversely.—Mr. MAURICE WEBB replied: As the trace of iodine will be very small the Medical Research Council think that adverse effects will be most unlikely; but my Food Standards Committee will bear this point in mind when considering representations about the proposed changes.

X-ray Film for Hospitals

Mr. N. N. DODDS asked the President of the Board of Trade whether he was aware of the shortage of X-ray film; and what steps he proposed to take to increase supplies to hospitals.—Mr. HAROLD WILSON replied: I am not aware that there is now any significant shortage of X-ray film. Production continues to increase and home users still have priority. No hospital need now be without supplies.

Accommodation for Aged

Mr. GEORGE THOMAS asked the Minister of Health the number of aged and chronic sick people who were housed in mental institutions in Wales because no other hospital accommodation was available; and what steps he was taking to relieve this problem.—Mr. BEVAN replied: I am not aware that any aged persons not suffering from mental infirmity are being housed in mental institutions in Wales; but I understand that there are, in those institutions, some 663 persons over the age of 65 who are suffering from mental infirmity, but could be appropriately accommodated elsewhere if suitable alternative accommodation were available. I have recently issued to the regional hospital boards some suggestions as to the provision of alternative accommodation for aged persons suffering from mental infirmity.

Medresco Hearing-aids

Replying to a question Mr. BEVAN stated that about 75,000 'Medresco' hearing-aids had now been supplied under the National Health Service.

Dentists in the N.H.S.

In answer to a question Mr. BEVAN stated that on Jan. 1, 1950, there were 9495 dentists on the dental lists in England and Wales, of whom 669 were assistants.

Obituary

BENJAMIN ALFRED PETERS

B.A., M.D. CAMB., D.P.H.

Dr. B. A. Peters, who died on May 8, had retired from the post of medical superintendent of Ham Green Hospital less than two years ago, and with the happy coöperation of his friend and successor Dr. James Macrae he was still pursuing a piece of biochemical research on the body's reaction to disease.

Born at Dundalk in 1882, the son of the late Rev. George Peters, he was educated at Liverpool College and Liverpool University before he went up to Jesus College, Cambridge, in 1901. The next two years he rowed in his college boat. In 1908 he graduated B.CHIR., taking his M.B. and D.P.H. in 1910 and his M.D. in 1913.

After serving on the resident staff of the city hospitals of his native town, Liverpool, he went to Bristol in 1910 as resident medical officer to Ham Green. The history of the growth of that hospital is also the story of his achievements. From 200 beds it grew to become a model fever-hospital-sanatorium of 500 beds with an auxiliary hospital of 108 beds at Charterhouse. The only break in his span of office was his service with the R.A.M.C. during the 1914–18 war as bacteriologist to the 14th General Hospital. In 1930 he was given the status of medical superintendent at Ham Green.

R. H. P. writes: "Dr. Peters has made some notable contributions to our knowledge regarding the treatment and prevention of the infectious diseases—in particular diphtheria and the streptococcal infections. He was a member of the subcommittee on cross-infection in hospital wards of the Preventive Medicine Committee of the Medical Research Council. The University of Bristol recognised his contribution to research by awarding him the Markham Skerritt prize and by making him a reader in infectious diseases. Among his colleagues and his patients he had many friends, and this was made evident when he retired from Ham Green. He came to the rescue of many of his medical colleagues and his clinical advice was much sought after. Although fond of sport, especially tennis at which he excelled, Dr. Peters was shy and retiring by nature and withdrew to his books whenever he had the opportunity, and in his retirement at Nailsea his research work and his garden kept him fully occupied and happy."

Dr. Peters married Sylvia, daughter of Dr. J. C. Heaven, who survives him with a daughter.

In England Now

A Running Commentary by Peripatetic Correspondents

STRANGE things often happen to doctors and I doubt if my story is unique. Being a mere obstetric house-surgeon, I get an off-duty weekend about once a month; but, of course, Friday is always a busy day, and as I'm preparing to make the inevitable dash for the 4.35 there will certainly be a couple of perineums to be stitched. This Friday was no exception. The 4.35 was, however, late, and by the time it arrived my puffing and blowing had subsided and my pulse was again at its normal 72. I leant back in a corner seat and settled down to enjoy the spring colours of the Garden of England and to see what I could of the stringing of the hops. But my enjoyment of Nature was rather spoilt by the hostile atmosphere in the compartment, for a cold and unfriendly stare was evident from the prim and proper middle-aged lady sitting opposite me. I noticed her occasional glance at my feet, and with some embarrassment (that sort of thing had happened before) I too glanced down; but no, both my socks bore the same bright red and yellow check pattern. For the whole of the half-hour journey to the next stop my fellow traveller fixed me with her hostile stare, and then, as the train was about to start again, she jumped up with sudden decision and leapt on to the platform. I settled back with a sigh of relief.

As I passed through the ticket barrier at Victoria, a well-dressed gentleman approached me and asked whether I would mind accompanying him to the station-master's office. Yes, I did mind; but he produced evidence of being a railway policeman, so I thought it wise to go with him. I soon learnt that a lady had telephoned a description of a young man whom she suspected of having recently committed some awful and horrible crime. Would I be good enough to explain? With a little loss of dignity, I had to admit that in the pre-weekend rush I had broken the labour-ward rules and not worn the surgeon's rubber boots for the afternoon's sewings-up. That was why the lower ends of my new flannel trousers were so bespattered with human blood stains.

I must remember to write to the Ethical Committee and ask whether I should sue for defamation of character or offer compensation to the lady for her two hours' wait for the next train.

* * *

This discussion about the capacity of various orifices reminds me of a friend who was called down to Casualty one night to see a deaf mute. His pencilled complaint was that for two days he had had a bottle in his rectum, and was unable to defæcate. My colleague removed a glass bottle, and, there being a rule in force at that time that all surgical specimens were to be sent for biopsy, duly dispatched it to the pathologist. There the story must end, for that morbid gentleman, having no sense of humour, threw the bottle away. It was a pity, for if he had examined it I have no doubt that he would have found a remarkable degree of hyaline change.

* * *

My grandmother had a theory that dogs resemble their owners, either because people tend to choose a dog with characteristics similar to their own or because the dog becomes adapted to his human. The same thing applies to people and their cars: there seem to be definite types that drive various makes of car.

The owner who invests in a Costyn, for example, is mild, donnish, clerical—or a maiden lady. The Pullsley 16 or 25 is driven by the hard, ruthless, self-made man; he thrusts past lesser fry, edging them into the ditch, and cuts in ferociously. The G.M. is driven by sweet young things with Jacqmar scarves, or by long-haired young men in hacking coats and suède shoes. The old round-nosed Boris Fowley is steered along, bang in the middle of the road and at a maximum speed of 20 m.p.h., by a character who wears a pork-pie hat or a bowler rammed fiercely down over his ears, from which hair is sprouting. He sits bolt upright at the wheel, and his little, piggy eyes shoot suspicious glances at anyone trying to overtake. His radiator boils steadily.

The small saloon car, of any brand, confers fertility on owner, to judge by the number of such cars seen at a ekend in which Papa at the wheel, like a rock in stormy sea. emerges dripping, now and then. from a th of small children. The Victory convertible is driven people who have obviously got out of *Vogue* or the *tler*—the wrong side.

However. I realised only the other day, when I got held in a traffic jam. how unscientific these generalisations e. A huge American car purred alongside me, and the onde at the wheel (*left-hand drive*) glanced down at and then remarked, too loudly. to her Stewart angerish escort, " Do look, Sweet—just a too-perfect bstandard Eight type ! "

* * *

The long dreary lists of references that are the postript of a good many medical articles today are of tle interest to the average reader. though they are doubt a godsend to the writers of subsequent articles, pecially M.D. theses. At the present rate of growth will not be long before the man who can find a column two of original remarks to make will be appending me sixteen pages of classified references: so would not relieve the strain and tedium if reference lists were stefully interspersed with photographs and cartoons the authors cited ? I admit these would sometimes hard to find. but they would soon be sent out autoatically with the reprints ; or. like the references emselves, could cheerfully be copied from previous apers. Apart from their amusement value these poraits would often enable one to judge the reliability the authors at a glance. Whether one's judgment ould be fair is another matter.

* * *

The other day I went to the office of the Administrative ssistant to pay my hospital telephone bill. The clerk ook the account and my shilling. checked the reference umber and my name, referred to a ledger. took down nother book and next a book of receipt forms, filled in he five-by-eight page in the latter and then the counteroil, and tearing out the completed receipt, fixed it to he bill with a stapling machine. Including remarks bout the weather the whole process occupied seven inutes, which led me to observe that the payment of the hilling had cost the service about sixpence in paper nd perhaps more in time. " But," said the clerk." you only see one side of the business. When this hilling reaches the finance department they may have man working on it all day." I'm afraid he was pulling ny leg. But the incident made me wonder whether here isn't some low limit below which it doesn't pay he hospital to collect its debts. Two bob is the ninimum on the tote ; what ought to be the low limit n hospital accounting ?

Letters to the Editor

REGISTER OF COMPLAINTS

SIR,—Your columns contain week by week many trenchant criticisms of the adverse effect that hospital administration is producing on the status and work of members of hospital staffs. Some of the deleterious effects might have been avoided if the administrators had hearkened to, or taken the advice of, knowledgeable and experienced members of the profession.

A grave instance of intervention without consultation with organisations representative of the profession is to be found in a current proposal by a group hospital management committee to establish a register of complaints. In this register it is required that there will be recorded the complaints made by inpatients or outpatients with regard to their care and treatment. An administrative officer will be responsible for maintaining a register at each hospital in his unit, for informing the departmental officers of its existence and purpose, and for stressing the importance of recording the full facts of actual complaints received or instances likely to give rise to complaints. The registers are to be made easily accessible to all departmental officers. It is emphasised in a circular that the regional hospital board, through hospital management committees, is obliged to ensure the admission to hospital of emergency cases. Out of this responsibility, it is urged that criticism will undoubtedly arise from time to time when a patient is refused admission in circumstances that appear to constitute an emergency.

It is also stated that the complaints register, when prepared and set in operation, should be kept in the casualty department or receiving-room of each hospital, so that the medical officer responsible for receiving emergency cases could readily record particulars of every case in the register when complaint is made concerning the action taken by the hospital officials relevant to admission.

More serious still, however, is the obligation cast upon members of the staff to ensure that there is readily available in the register of complaints an answer to criticism that may be raised by questions in Parliament or by letters to Members of Parliament, the Minister of Health, the management committee, or the press. Administrative officers are instructed that extracts of records made in the register during the previous month are to be forwarded to the secretary of the management committee on the third day of each month. The actual registers are now being printed and will be made available as soon as practicable.

The foregoing procedure is fraught with danger for the medical staff of the hospitals concerned, and would doubtless be held in horror by solicitors who have anything to do with the protection of the profession in medicolegal cases. It may be that the management committee is legally competent to give directions for the maintenance of a book of this order. The register will probably work unfairly, since a conscientious medical officer might report every complaint he received from a patient, whilst another less conscientious, and even alive to the dangers of the situation, would report little or nothing.

Some of these entries in the register might be held by the lawyers to be defamatory, and the practitioner concerned might have a right of action if he has suffered thereby. Presumably, qualified privilege will attach to this register, but its availability for examination by interested parties is of great significance. The procedure known to the lawyers as " discovery of documents " could doubtless be employed to gain information on all hospital records pertinent to a case that is proceeding to a hearing in our courts. The medical officer may

X-ray Film for Hospitals

Mr. N. N. DODDS asked the President of the Board of Trade whether he was aware of the shortage of X-ray film; and what steps he proposed to take to increase supplies to hospitals.—Mr. HAROLD WILSON replied: I am not aware that there is now any significant shortage of X-ray film. Production continues to increase and home users still have priority. No hospital need now be without supplies.

Accommodation for Aged

Mr. GEORGE THOMAS asked the Minister of Health the number of aged and chronic sick people who were housed in mental institutions in Wales because no other hospital accommodation was available; and what steps he was taking to relieve this problem.—Mr. BEVAN replied: I am not aware that any aged persons not suffering from mental infirmity are being housed in mental institutions in Wales; but I understand that there are, in those institutions, some 663 persons over the age of 65 who are suffering from mental infirmity, but could be appropriately accommodated elsewhere if suitable alternative accommodation were available. I have recently issued to the regional hospital boards some suggestions as to the provision of alternative accommodation for aged persons suffering from mental infirmity.

Medresco Hearing-aids

Replying to a question Mr. BEVAN stated that about 75,000 'Medresco' hearing-aids had now been supplied under the National Health Service.

Dentists in the N.H.S.

In answer to a question Mr. BEVAN stated that on Jan. 1, 1950, there were 9495 dentists on the dental lists in England and Wales, of whom 669 were assistants.

Obituary

BENJAMIN ALFRED PETERS

B.A., M.D. CAMB., D.P.H.

Dr. B. A. Peters, who died on May 8, had retired from the post of medical superintendent of Ham Green Hospital less than two years ago, and with the happy coöperation of his friend and successor Dr. James Macrae he was still pursuing a piece of biochemical research on the body's reaction to disease.

Born at Dundalk in 1882, the son of the late Rev. George Peters, he was educated at Liverpool College and Liverpool University before he went up to Jesus College, Cambridge, in 1901. The next two years he rowed in his college boat. In 1908 he graduated B.CHIR., taking his M.B. and D.P.H. in 1910 and his M.D. in 1913.

After serving on the resident staff of the city hospitals of his native town, Liverpool, he went to Bristol in 1910 as resident medical officer to Ham Green. The history of the growth of that hospital is also the story of his achievements. From 200 beds it grew to become a model fever-hospital-sanatorium of 500 beds with an auxiliary hospital of 108 beds at Charterhouse. The only break in his span of office was his service with the R.A.M.C. during the 1914–18 war as bacteriologist to the 14th General Hospital. In 1930 he was given the status of medical superintendent at Ham Green.

R. H. P. writes: "Dr. Peters has made some notable contributions to our knowledge regarding the treatment and prevention of the infectious diseases—in particular diphtheria and the streptococcal infections. He was a member of the subcommittee on cross-infection in hospital wards of the Preventive Medicine Committee of the Medical Research Council. The University of Bristol recognised his contribution to research by awarding him the Markham Skerritt prize and by making him a reader in infectious diseases. Among his colleagues and his patients he had many friends, and this was made evident when he retired from Ham Green. He came to the rescue of many of his medical colleagues and his clinical advice was much sought after. Although fond of sport, especially tennis at which he excelled, Dr. Peters was shy and retiring by nature and withdrew to his books whenever he had the opportunity, and in his retirement at Nailsea his research work and his garden kept him fully occupied and happy."

Dr. Peters married Sylvia, daughter of Dr. J. C. Heaven, who survives him with a daughter.

In England Now

A Running Commentary by Peripatetic Correspondents

STRANGE things often happen to doctors and I doubt if my story is unique. Being a mere obstetric house-surgeon, I get an off-duty weekend about once a month; but, of course, Friday is always a busy day, and as I'm preparing to make the inevitable dash for the 4.35 there will certainly be a couple of perineums to be stitched. This Friday was no exception. The 4.35 was, however, late, and by the time it arrived my puffing and blowing had subsided and my pulse was again at its normal 72. I leant back in a corner seat and settled down to enjoy the spring colours of the Garden of England and to see what I could of the stringing of the hops. But my enjoyment of Nature was rather spoilt by the hostile atmosphere in the compartment, for a cold and unfriendly stare was evident from the prim and proper middle-aged lady sitting opposite me. I noticed her occasional glance at my feet, and with some embarrassment (that sort of thing had happened before) I too glanced down; but no, both my socks bore the same bright red and yellow check pattern. For the whole of the half-hour journey to the next stop my fellow traveller fixed me with her hostile stare, and then, as the train was about to start again, she jumped up with sudden decision and leapt on to the platform. I settled back with a sigh of relief.

As I passed through the ticket barrier at Victoria, a well-dressed gentleman approached me and asked whether I would mind accompanying him to the station-master's office. Yes, I did mind; but he produced evidence of being a railway policeman, so I thought it wise to go with him. I soon learnt that a lady had telephoned a description of a young man whom she suspected of having recently committed some awful and horrible crime. Would I be good enough to explain? With a little loss of dignity, I had to admit that in the pre-weekend rush I had broken the labour-ward rules and not worn the surgeon's rubber boots for the afternoon's sewings-up. That was why the lower ends of my new flannel trousers were so bespattered with human blood stains.

I must remember to write to the Ethical Committee and ask whether I should sue for defamation of character or offer compensation to the lady for her two hours' wait for the next train.

* * *

This discussion about the capacity of various orifices reminds me of a friend who was called down to Casualty one night to see a deaf mute. His pencilled complaint was that for two days he had had a bottle in his rectum, and was unable to defæcate. My colleague removed a glass bottle, and, there being a rule in force at that time that all surgical specimens were to be sent for biopsy, duly dispatched it to the pathologist. There the story must end, for that morbid gentleman, having no sense of humour, threw the bottle away. It was a pity, for if he had examined it I have no doubt that he would have found a remarkable degree of hyaline change.

* * *

My grandmother had a theory that dogs resemble their owners, either because people tend to choose a dog with characteristics similar to their own or because the dog becomes adapted to his human. The same thing applies to people and their cars: there seem to be definite types that drive various makes of car.

The owner who invests in a Costyn, for example, is mild, donnish, clerical—or a maiden lady. The Pullsley 16 or 25 is driven by the hard, ruthless, self-made man; he thrusts past lesser fry, edging them into the ditch, and cuts in ferociously. The G.M. is driven by sweet young things with Jacqmar scarves, or by long-haired young men in hacking coats and suède shoes. The old round-nosed Boris Fowley is steered along, bang in the middle of the road and at a maximum speed of 20 m.p.h., by a character who wears a pork-pie hat or a bowler rammed fiercely down over his ears, from which hair is sprouting. He sits bolt upright at the wheel, and his little, piggy eyes shoot suspicious glances at anyone trying to overtake. His radiator boils steadily.

Letters to the Editor

REGISTER OF COMPLAINTS

SIR,—Your columns contain week by week many trenchant criticisms of the adverse effect that hospital administration is producing on the status and work of members of hospital staffs. Some of the deleterious effects might have been avoided if the administrators had hearkened to, or taken the advice of, knowledgeable and experienced members of the profession.

A grave instance of intervention without consultation with organisations representative of the profession is to be found in a current proposal by a group hospital management committee to establish a register of complaints. In this register it is required that there will be recorded the complaints made by inpatients or outpatients with regard to their care and treatment. An administrative officer will be responsible for maintaining a register at each hospital in his unit, for informing the departmental officers of its existence and purpose, and for stressing the importance of recording the full facts of actual complaints received or instances likely to give rise to complaints. The registers are to be made easily accessible to all departmental officers. It is emphasised in a circular that the regional hospital board, through hospital management committees, is obliged to ensure the admission to hospital of emergency cases. Out of this responsibility, it is urged that criticism will undoubtedly arise from time to time when a patient is refused admission in circumstances that appear to constitute an emergency.

It is also stated that the complaints register, when prepared and set in operation, should be kept in the casualty department or receiving-room of each hospital, so that the medical officer responsible for receiving emergency cases could readily record particulars of every case in the register when complaint is made concerning the action taken by the hospital officials relevant to admission.

More serious still, however, is the obligation cast upon members of the staff to ensure that there is readily available in the register of complaints an answer to criticism that may be raised by questions in Parliament or by letters to Members of Parliament, the Minister of Health, the management committee, or the press. Administrative officers are instructed that extracts of records made in the register during the previous month are to be forwarded to the secretary of the management committee on the third day of each month. The actual registers are now being printed and will be made available as soon as practicable.

The foregoing procedure is fraught with danger for the medical staff of the hospitals concerned, and would doubtless be held in horror by solicitors who have anything to do with the protection of the profession in medicolegal cases. It may be that the management committee is legally competent to give directions for the maintenance of a book of this order. The register will probably work unfairly, since a conscientious medical officer might report every complaint he received from a patient, whilst another less conscientious, and even alive to the dangers of the situation, would report little or nothing.

Some of these entries in the register might be held by the lawyers to be defamatory, and the practitioner concerned might have a right of action if he has suffered thereby. Presumably, qualified privilege will attach to this register, but its availability for examination by interested parties is of great significance. The procedure known to the lawyers as " discovery of documents " could doubtless be employed to gain information on all hospital records pertinent to a case that is proceeding to a hearing in our courts. The medical officer may thoughtlessly and ill-advisedly record a complaint in such a manner as to place himself in the wrong, whereas on further and fuller investigation it might transpire that he was not in any way blameworthy for what had occurred. This in effect means that medical officers may unintentionally and in good faith provide ample material for a prospective litigant to establish negligence in the discharge of professional obligations.

Steps are being taken to draw the attention of the Consultants and Specialists Committee to this innovation of the administrators in the hope that that committee may regard the matter of sufficient gravity to warrant the presentation of a protest to the Ministry of Health. The council of the Medical Defence Union has adopted a resolution condemning the practice of the establishment of a complaints register in hospitals and it hopes the British Medical Association will be successful in persuading the Ministry of Health to recognise the dangers of the procedure proposed to be followed.

Medical Defence Union,
49, Bedford Square, London, W.C.1.
ROBERT FORBES
Secretary.

ANTI-HISTAMINE DRUGS AND THE TUBERCULIN REACTION

SIR,—As your annotation of Jan. 28 showed, various workers [1] [2] have failed to demonstrate in man a reduction in skin sensitivity to tuberculin after administration of anti-histamine drugs. To provide more conclusive evidence on this point I repeated the experiment using large doses of 'Anthisan.' There were twenty subjects in the series, including five controls, unknown to the observer, and selected at random by the ward sisters. The subjects were inpatients at Preston Hall Sanatorium, and were not receiving streptomycin or *p*-aminosalicylic acid at the time. After the initial Mantoux test (using 0·1 ml. Koch's Old Tuberculin injected intradermally and read at 48 and 72 hours) anthisan was given by mouth (0·3 g. daily for the first day and 0·6 g. daily subsequently, in divided doses). After 4 days the skin tests were repeated and anthisan continued until the results were read. The findings were as follows:

Case		Mantoux		
		1 in 10,000	1 in 1000	1 in 100
Controls ..	1	+		
		+		
	2		+	
			+	
	3		? +	+
			+	
	4, 5			+
				+
Test subjects	6–14	+		
		+		
	15	+		
		? +		
	16–18		+	
			+	
	19		+	
				+
	20			+
			+	

In each case the second reading is recorded on the line below the first.
+ = weal 5 mm. or more in diameter.

It will be seen that the second result was identical with the first in four out of five controls and in twelve out of fifteen test subjects. In one control and one test subject, results were equivocal. Sensitivity appeared to be increased in one test subject and decreased in another.

The Mantoux reaction is a crude instrument for quantitative measurements, as pointed out by Long and Miles,[3] and the method they describe of plotting log dose against lesion diameter may be of more value. The results obtained here support earlier findings that anthisan does not affect the Mantoux reaction.

My thanks are due to Dr. F. Temple Clive for kindly granting facilities for this investigation.

London, W.12. DENIS ABELSON.

HISTORY OF NURSING

SIR,—Your correspondent of May 13, discussing Mrs. L. R. Seymer's book, says that many today see grave ground for anxiety in the fact that the rise in numbers of nurses has not been accompanied by a rise in the quality of nurses or of nursing. This is certainly true, and is largely because it is now taken for granted in this country that the chief part of the nursing staff of the hospital must be drawn from the ranks of the student nurses. This leads to a grave situation in which, in order to keep the wards of the hospital open, candidates for nursing are accepted as "pairs of hands," and little attention is paid to their quality and their suitability for the profession for which they are training. So long as this danger is unrecognised, and so long as inducement from high quarters is given to attract all and sundry into the nursing profession by giving large initial salaries during training, and by other means, so long will this anxiety remain, and so long is there likely to be deterioration in the standard of British nursing.

No doctor or nurse can read the recently published *A Voice Through the Clouds*, by Denton Welch, without a sense of uneasiness. To anyone who knows conditions within our hospitals today it is clear that much of the mental suffering the author underwent in the earlier stages of his long illness was due to the failure of young and frightened so-called student nurses, who were carrying responsibility greater than their age or experience justified and so were unable to deal adequately with the abnormal mental condition and great physical and mental distress of their patient.

The large percentage of failures in the State Examination quoted by your correspondent is due as much to the poor type of candidate, who would inevitably have wasted from the nursing profession, as to the high standard demanded in that examination. Miss Nightingale, when refusing her approval to State registration in 1892, qualified her disapproval by saying—"Twenty or thirty years hence, when so much progress has been made that our present time is looked back upon as the time of bad nursing, this registration might do." I have taught girls in different types of hospitals, from many different types of homes, and from different educational backgrounds, and I have never found anyone who has real purpose and character, and ability to carry the responsibilities of the State-registered nurse, who has failed to do so through failure to pass her examination, though she may not have been successful at her first attempt.

The four great essentials for the nursing of the future are:

1. Greater emphasis on the education of the nurse, and less on the employment of student labour in the hospitals.
2. More careful selection of candidates with regard to intelligence and practical ability.
3. Careful revision of the syllabus of the General Nursing Council, so that all the theoretical background given is closely related to the practical work of the wards and in the public-health field.
4. Retention of professional responsibility and the administration of nurse training schools in the hands of the nursing profession itself.

There is indeed room for a second volume of Mrs. Seymer's *History of Nursing*, in which these and other problems affecting the profession today could be fully and critically discussed.

CONTINUOUS DRIP TREATMENT OF PEPTIC ULCER

SIR,—Dr. Clark (April 29) has shown that although intragastric drips of milk and of alkali are relatively effective in reducing the concentration of hydrogen ions in the gastric contents, the pain of refractory duodenal ulceration is frequently relieved by such treatment. This observation is susceptible to at least two interpretations: (1) that only a minor reduction in the acidity of the gastric contents is necessary to relieve pain, as suggested by Dr. Clark; or (2) that some condition of the stomach associated with its secretory activity—e.g., vascularity—causes the pain, and that this activity is reduced by the fat content of the milk.

We have confirmed Dr. Clark's observations in three patients with duodenal ulcers who were receiving milk drips. In addition we have been able to assess the rate of gastric secretion whilst the drip was being given. For example, in one patient, when the total gastric contents was withdrawn at intervals, the acidity was greater than pH 1·5 in 11 samples out of 25 spread over six days although he had no pain during this period. The mean concentration of chloride in the gastric contents for this period was 127 milli-equivalents per litre (clinical units).

Knowing the maximum concentration of Cl^- in the gastric juice to be 170 milli-equivalents per litre, the concentration of Cl^- in the milk drip to be 30 milli-equivalents, and the volume of the milk drip used in each subject to be 5 pints (2·8 litres) per 18 hours, it was possible to calculate the rate of secretion of gastric juice in each case. In the three subjects the rates of secretion were estimated to be 350 ml., 194 ml., and 183 ml. per hour. If, as seems possible, the concentration of Cl^- in the gastric juice was less than the theoretical maximum of 170 milli-equivalents per litre, then the calculated volume of secretion would be correspondingly greater. Thus as a stimulus of secretion the milk drip was about as effective as the usual dose of histamine given as a test of gastric secretion—which seems to dispose of the idea that milk significantly inhibits the secretory activity of the stomach. This leaves Dr. Clark's suggestion that only small changes in pH are necessary to relieve the pain; or, alternatively, the fat or curd in the milk may mechanically protect the ulcer from the acid.

We hope that this letter will provoke discussion.

PROTECTION OF SURGEONS

SIR,—Having recently been forced to give considerable attention to the protection of young surgeons in this country, it seems to me advisable to publish some points about the present position in general and the question of "cover" in particular.

The first point to be appreciated is that any claim against a hospital will be answered by the Ministry of Health. The Ministry in its turn assumes no responsibility for an act of any member of the medical staff, and will in fact bring him in as a third party in the action. This will have the effect of transferring the action from the Ministry to the doctor; and he will find not only that he is not supported, as he was in the old days, by the hospital and its nursing staff, but also that they are Ministry witnesses and can be used against him. It is therefore vitally essential that he should provide himself with all the assistance he possibly can.

The unenviable position in which the doctor is being placed becomes particularly unfortunate when a visitor from overseas is concerned. Having returned to his own country after a period here during which time he may have performed some operation, at any time up to six years subsequently a claim arising out of that operation can be transferred by the Ministry and laid at his door.

It is therefore good to be able to report that the Medical Defence Union and the Medical Protection Society have recently made special provisions to cover visitors from overseas, and it behoves such visitors to take advantage of these provisions. An overseas doctor who has studied or practised in this country and who desires to maintain protection should make an application for either a retired life membership subscription (Medical Defence Union) or a combined subscription (Medical Protection Society). The full details are available from Dr. Robert Forbes, Medical Defence Union, 49, Bedford Square, London, W.C.1, and from Dr. A. R. French, Medical Protection Society, Victory House, Leicester Square, London, W.C.2.

University of Liverpool.

B. L. McFARLAND.

TUBERCULOSIS MORTALITY

SIR,—Mr. Daw's interesting and important letter in your issue of April 29, referring to the method of examination of tuberculosis mortality in successive "generations" or "cohorts," developed by Frost,[1] appears to have started a discussion as to who first applied the method to British mortality figures. The answer is: Andvord, of Oslo, the originator of the idea, in 1930.[2]

Whittington Hospital, London, N.19.

A. L. JACOBS.

TEACHING OF PUBLIC HEALTH

SIR,—In your issue of May 13 (p. 934) you record Prof. J. M. Mackintosh's statement on the ultimate dispersal of students from the London School of Hygiene who were awarded the D.P.H.; and the general tone of the commentary is one of regret that of 90 diploma graduates in the past two years only 15 have been recruited to the public-health service in this country.

It seems to me that this somewhat restricted view of the ultimate usefulness of the course for the D.P.H. is unfortunate. Essentially, the value of the course is that it brings into focus the social, environmental, and epidemiological aspects of health and disease. Need there, therefore, be any lament that out of the 22 successful British students last year all but 7 have found their way into work other than that of local government?

Can one imagine a better all-round postgraduate course for general practitioners of medicine than a D.P.H. curriculum containing, as it should, instruction in the epidemiologies of the home, the factory, the school—and even the hospital? Should not the general practitioner have every opportunity of learning the ideas inculcated in the D.P.H. course? I suggest that the head of a department responsible for the diploma course should not be discouraged because his successful students wander into paths other than that of local government, but should be glad to think that some at least of them, as general practitioners, will make good use of his instruction when the present difficulties in general practice subside and the practitioner is able to play his proper part in the public health of the future. I hope that Professor Mackintosh will in fact come to regard the D.P.H. as a very useful extra qualification for the general practitioner; perhaps he might even agree that it is unfortunate that the course is whole-time, since this must prevent many doctors from taking it. If I may slightly amend Professor Mackintosh's wording, the purpose of the course in public health should not be to provide training for consultants in preventive medicine, but to offer opportunities for the making of good general practitioners in domiciliary health.

PREGNANCY AND PULMONARY TUBERCULOSIS

SIR,—In his presidential address to the Sheffield Regional Chest Society, published in your issue of April 15, Dr. Midgley Turner summarised his very extensive observations regarding the influence of pregnancy on pulmonary tuberculosis, and advanced the theory that the increased risks in the first four months of pregnancy are due to the excess of gonadotropins, and in the puerperium to the sudden withdrawal of the favourable influence of the œstrogens.

This excellent contribution has, however, completely ignored a further powerful endocrine factor—the well-marked hypertrophy of the adrenal cortex and hypersecretion of its sugar hormones which takes place in pregnancy. Enlargement of the gland has long been known to occur, and it has been shown [1] that the urinary "corticoids," which indicate the amount of the sugar hormones secreted, increase greatly in the first trimester, along with the increase in the gonadotropins, and return to about normal levels by the 100th–120th day, coinciding roughly with the fall in the gonadotropins. Between the 140th and 160th days the corticoid excretion again rises, in company with the œstrogens and pregnanediol, reaching in the later months the very high levels found in Cushing's syndrome or after severe injury; excretion in the last month declines somewhat, and in the puerperium it falls sharply to normal. There is doubt as to whether the fœtal cortex plays any significant part.

There seems good reason for the belief that this most pronounced response of the adrenal cortex to the stress of pregnancy explains its favourable effects on rheumatoid arthritis and partial adrenal insufficiency; the decreased glucose tolerance of the normal subject and the increased insulin requirements of the diabetic; and the occasional ketonuria and glycosuria, the acidosis, the well-being of the later months, and, in all probability, many other normal and possibly abnormal features of pregnancy.

Recent observations that 'Cortisone,' or the sugar hormones secreted in response to the adrenocorticotropic hormone (A.C.T.H.), have an inhibitory effect on wound healing and the formation of granulation tissue,[2] and on growth as a whole,[3] and their effects on lesions of collagen, allied with the weakness of the supporting tissues and striæ found in Cushing's syndrome, suggest most strongly that abdominal enlargement is only partly the cause of the appearance of striæ gravidarum.

The evidence produced by Rich [4] and others in recent years is strongly in favour of hypersensitivity being the main cause of the destruction produced by the tubercle bacillus, so that the damage is out of all proportion to any defensive value of the hypersensitive state; and it has now been shown that cortisone or A.C.T.H. will non-specifically depress both the tuberculin [5] and the anaphylactic [6] types of hypersensitivity.

In the light of these findings it seems probable that pregnancy may have a dual influence on tuberculosis—by decreasing hypersensitivity and increasing the non-specific resistance, while at the same time retarding healing or even breaking down fibrosis. Thus, though the former effect may be beneficial, the latter may cause the breakdown of a quiescent lesion, or the rapid progression of an active one, with wide dissemination of the disease. It is notable that the reactivation of quiescent lesions has already been reported as a result of using A.C.T.H. or cortisone.[7] The available evidence [4] regarding the influence of pregnancy on hypersensitivity is, however, conflicting and unsatisfactory, though a decisive effect has been demonstrated experimentally.[5]

The reasons for the hypertrophy and hypersecretion of the adrenal cortex in pregnancy are not yet clear, though it is well established that œstrogens will cause hypertrophy of the cortex in the experimental animal.[8] This cannot be the sole reason for this feature of pregnancy, and there can be no doubt that the adrenal cortex must share in the reaction of the whole body to the stress of pregnancy and labour—a reaction which involves *the participation of the endocrine system as a whole,* and not of the sexual functions and glands alone. Furthermore, it is well known that the thyroid gland is also hyperfunctioning in pregnancy, and that its hormone will cause cortical hypertrophy and hypersecretion, within certain limits.

The experiments of Lurie et al.[9] are of great interest: but they point out that previous reports regarding the influence of œstrogens and gonadotropins are conflicting, and that as the use of a special inbred strain of rabbit was necessary to obtain a clear-cut result the effects of these hormones on the disease cannot be great. Though they failed to demonstrate unequivocal evidence of increased cortical activity in the rabbit as a result of administering doses of œstrogen stated to be far in excess of physiological levels, close perusal of their papers leaves little doubt that some increase did occur. Also, since the degree of amyloid degeneration, especially in the cortex, was much less in the œstrogen-treated animals, it is reasonable to assume that cortical function was much better in these animals. The adverse effect of gonadotropin remains to be explained, but the small number of animals and the difficulties with anti-hormone formation which were encountered make it difficult to regard the results as conclusive.

The administration of cortical extracts was shown some years ago [10] to exert a very favourable effect on both lesions and survival-time of the guineapig with tuberculosis; but in this experiment, just as in those referred to above, the infection was a primary one. On account of the possible dual nature of the action of the sugar hormones on a *secondary* infection, it would appear that the effects of these hormones on a primary infection in the experimental animal are most unlikely to be applicable to the disease in man.

It is not possible to rule out the sex hormones as playing a part in the influence of pregnancy on tuberculosis, especially in view of the well-recognised increase in the incidence of the disease following the menarche, as compared with the male. Nevertheless, it would seem most probable that in pregnancy the great excess of the sugar hormones exerts much more influence on the course of the disease than do the sex hormones. It may be postulated that the first rise in the secretion of the sugar hormones may, in conjunction with the initial strain of pregnancy, light up a quiescent lesion or cause the regression of an active lesion, so that the peak of incidence in the fourth month found by Dr. Turner may be due, at least partly, to the decrease in cortical secretion at this time. The low incidence during the rest of pregnancy may perhaps be explained by the effect of the great excess of sugar hormones in raising the non-specific resistance, or by a decline in hypersensitivity. Thus it is possible that the disease may be masked, only to become manifest after delivery when hypersecretion ceases, accompanied by a degree of general exhaustion.

10. Pottenger, F. M., Pottenger, J. E. *Endocrinology,* 1937, 21, 529.

It would be most unwise to be dogmatic regarding these points, as a multiplicity of factors may influence he relationship between pregnancy and the disease.[4] Nevertheless, attention should be directed to the adrenal cortex as a factor which may be more powerful than is realised. It would seem possible that the dual nature of the influence which the hypersecretion of these powerful hormones in pregnancy may exert on the disease may explain why the individual case may either deteriorate or improve, though the figures for the group as a whole show that the prognosis is not significantly altered.

Edinburgh. H. MORROW BROWN.

ANOMALIES OF SALARY

SIR,—I must express the concern of the Institution of Professional Civil Servants at the line taken in your leading article last week. We have no desire at all to comment on your decision about the publication of Government advertisements. That is patently for you and it would be improper for us to offer an opinion. In the course of your decision, however, you do in fact, even though it may not be your intention, enter the lists against the Civil Service medical officer.

The proposal by the Chancellor that the committee should consider both the structure of the Civil Service and the salaries is an issue that we are shortly to discuss with one of his officers. What neither the Chancellor nor you appear to appreciate is that the structure and salaries are two separate and distinct questions and not one.

So far as salaries are concerned, Sir Will Spens in the two reports of his committees set out in clear and unmistakeable language his views about the remuneration of people in the medical profession. He does not in terms deal with the salaried medical officer, but there is unlikely to be any dissent from the view that the salaried medical officer must have a salary which is in scale with the remuneration open to his fellows, calculated on a different basis. As you quite rightly point out, however, there is not a proper relation between the two, because even the standard and standing of the salaried medical profession will go down. In terms of a medical service, this seems to be an absurd state of affairs and one that ought not to be tolerated. It is our view, therefore, that there is no need for a new committee to adjudicate on what ought to be the salary of the medical officer but that Sir Will Spens, who has had all the advantages of previous research, is the best person to express a considered and authoritative view in this matter. The decision of a committee with Sir Will Spens would not, of course, be dissented from, but there seems to be something fundamentally wrong in any proposal that would place on a body totally different from that of the Spens Committees the work of determining the right level for a section of the salariat in the medical profession.

On particular points that you make, may I offer the following comments? You say that pressure is permissible when an individual employer does not apply some national scale. That, surely, is exactly what is happening here. There are only some 500 or 600 medical officers in the Civil Service. The vast bulk of the 40,000–50,000 medical people in the country are remunerated largely, if not wholly, from State funds through the National Health Service—that is to say, on scales which have been agreed by the Government. The claim that is being made for Civil Service medical officers is simply that these officers should be remunerated on the same basis as medical people in the National Health Service.

You also say that pressure can probably be *justified* when it is brought to bear on an employer who refuses to negotiate through the channels laid down for the purpose. That is exactly what has happened in this case. There is a machinery of negotiation between the institution and the Treasury, but we were told quite definitely and flatly by the Treasury spokesmen that they were not in a position to negotiate. They listened quite politely to what we had to say but they were certainly not negotiating; and indeed the Treasury officers were at pains to make it clear that they were not negotiating.

We are seriously concerned at the effect of what is happening in the medical Civil Service. There is already an undermining of efficiency, which must necessarily result where a service is undermanned. May I assure you that officers throughout the medical Civil Service feel themselves to be very wrongly treated? There would be no objection at all to a proposition that Sir Will Spens or the Spens Committees should in fact be asked to act as arbitrators or to be put in a position in which, say, Lord Chorley, was recently put in a consideration of the salary-scale of assistant secretaries—that is, his committee received evidence from the Association of First Division Civil Servants and from the Treasury and then gave its views as to what the salary-scale of assistant secretaries should be. The Government accepted the recommendations of the committee. There is a precisely similar set of circumstances vis-à-vis the Spens Committees, and it is on that basis that we should be very glad to see this issue referred to them for a decision; and there is no reason, if the Government were prepared, that such an arrangement should not be put in hand forthwith.

STANLEY MAYNE.

COINS, ORIFICES, &c.

SIR,—Now that Dr. Lloyd (May 13) has gone a long way towards meeting your peripatetic correspondent's request for a table relating the diameters of coins to the bodily orifices, I must point out the desperate need for a new table, drawn up by a panel of experts, correlating (1) degrees of dilatation of the full-term cervix, (2) fingers of the hand, and (3) coins of the realm. Consultants, nursing staff, and practitioners all use different terminologies and mensuration standards as the os dilates. A table like this would make a fine contribution to present-day obstetro-numismatics. And in view of the shrinking world, it might be as well to systematise the cervix in values of francs, marks, dollars, roubles, and others (at current rates of exchange, of course).

Cambridge. A. S. PLAYFAIR.

THE DEAF CHILD

SIR,—Recently I was reading Mrs. and Dr. Ewing's book on *Opportunity and the Deaf Child* (published in 1947) and found them saying that, when a child is deaf, dumb, and wordless, his intelligence is impoverished by the lack of language. In this they seem to me to overlook the imagination of the child. As a congenitally deaf person, I remember that, before I learnt to lip-read and to speak, my mind was filled with imagination. Naturally my thoughts were in pictures, but so are those of all children before they are able to speak. The difference is that we deaf go on like this for a longer period—until we are taught to speak. I do not think that any parent of a deaf-born child need fear that the mind of the child will remain blank until he achieves speech.

May I at the same time comment on a conclusion reached by the Ewings after much experiment—namely, that a pure-tone audiometer is unsuitable for any child under five years of age, so long as he shows no sign of "hearing." A deaf-born child, they say, must be trained to listen—i.e., to learn to hear—before his hearing can be tested. This I believe to be very true. My hearing amounts to practically nothing; yet, with a hearing-aid I am able to assimilate many sorts of sounds, to recognise some, and to locate them, although I am unable to understand human speech. But when I had my hearing tested on the pure-tone audiometer the sounds became meaningless, and it was extremely difficult for me to know whether I was still hearing, or had just finished hearing. How then can one expect a small deaf child, who perhaps has never heard before, to "hear" such meaningless sounds as are given out on the audiometer?

London, N.W.3. A. B. S. SPRIGGE.

MEDICAL TOUR OF INDIA

SIR,—As you are aware, many Indian medical men come to Great Britain for postgraduate studies, and from my own experience I know how much they appreciate the helpful coöperation shown to them by their English colleagues. When they go back to India they feel they are leaving behind some very good friends.

Now I, knowing both countries, have often thought it a pity that English doctors are able so rarely to visit India and so strengthen from this side the existing ties of friendship. In this thought I am not alone since, when I was last in India two years ago, many of the doctors I met said they would be as pleased to welcome English medical practitioners in India as they would themselves be to visit Great Britain. The chief obstacle is the cost—the return air fare is about £250, and to this must be added approximately the same amount for, say, three weeks' expenses.

Through the great kindness of friends in this country and in India, it will be possible for me to take a small party to India at the end of next September, for a 4–5 weeks' tour at a total cost of £185–190 each, including the return air fare. I shall be very pleased to hear from any medical men or women who are interested. All letters should reach me before June 15.

London, W.1. R. U. HINGORANI.

FLAXEDIL IN LARYNGEAL INTUBATION

SIR,—I should like to make a few remarks on Dr. Doughty's excellent article in your issue of May 13. I have used 'Flaxedil' for both abdominal and E.N.T. surgery in a large series of cases, and I find 80 mg. of flaxedil is too large an amount to give a patient in order to facilitate operation without delay.

The two essentials of anæsthesia for E.N.T. surgery are a perfect airway and a bloodless field. The near-perfect airway is secured with a large endotracheal tube, and this can easily be inserted with 40 mg. of flaxedil and 0·25–0·75 g. of thiopentone, depending upon the age and physique of the patient. The bloodless field is secured, not by pushing the nitrous oxide in a patient whose tidal volume is already diminished by the thiopentone and flaxedil, but by using trichlorethylene. This is done by passing the gases—5 litres of nitrous oxide and 2 litres of oxygen—intermittently through a Boyle's bottle with the plunger right up and containing 8 drachms of trichlorethylene. The trichlorethylene helps to prevent oozing from blood-vessels also. To obviate the risk of the patient breathing against resistance, and the build-up of carbon dioxide, I use the following piece of apparatus: a corrugated tube 18 in. long and $^{3}/_{4}$ in. in diameter attached to the endotracheal connection where the fresh gases enter, and open at the other end. The soundless respiration resulting is a sign of the perfect airway.

I object to the use of amethocaine, because of the risk of sensitivity or overdosage,[1] and I prefer to have the tube thinly lubricated with 10% 'Nupercaine' ointment. This is enough to prevent the cough reflex during operation, provided the tube is not moved; but on moving the tube at the end of the operation the cough reflex is present.

Birkenhead. GOUGH HUGHES.

Notes and News

JUBILEE OF LEBANON HOSPITAL FOR MENTAL DISEASES

AT the 51st annual meeting, which was held in London on April 28, Sir Ronald Storrs presided and Prof. Alexander Kennedy, who knows the hospital personally, presented a medical report by Dr. Manugian, deputy medical director. This showed that the work undertaken has increased and the financial position is more satisfactory. During 1949, 440 patients of twelve different nationalities were treated and the total income for the year was £61,000, of which £56,000 came from patients' fees and £1100 as a gift from the Lebanese government. But there is still leeway to be made up from the war years; the present admission rooms are being extended and new quarters for the doctors are being built, while plans for the near future include a residential block for nervous cases. Professor Kennedy said that the work at Asfuriyeh was known throughout the Middle East, and had left on him a lasting impression. The results were those of a modern mental hospital, setting and maintaining high standards. Treatment included electronarcosis and insulin. The ancient attitudes towards mental disease were hard and cruel: this hospital's great influence was through the example of patient work, technical skill, and kindliness. In opening a neuropsychiatric clinic in Beirut (6 miles away) it had developed its teaching of the community in understanding of the mentally afflicted and their problems. Another important function was the training of doctors and nurses for the Middle East—the former in liaison with the American and French universities in Beirut, the latter by means of an Asfuriyeh certificate course (3 years). From this hospital was thus spreading a movement for mental hygiene, prevention of disease, and coördinated mental-health services, and all the signs pointed to a great forward move at this jubilee period of its history, if support was forthcoming. The Lebanese minister-plenipotentiary, Mr. Victor Khouri, described the hospital as one of the most important medical centres of the Middle East. He was glad that in its efforts to survive the difficulties of the war years the hospital had had the help of his government, and he looked forward to further coöperation. Mr. Fadlo Hourani presented a cheque for £152 from the Lebanese community in Manchester. Miss Jane Gibb, matron from 1913 to 1946, recalled the arrival in early days of chained patients, often burned by red-hot pokers or cigarettes in order to "drive out the devil." Dr. R. W. Brigstocke and Dr. David Yellowlees, whose fathers attended the first public meeting in Beirut in 1896 and had been founder members of the Beirut and Glasgow committees respectively, took part, and the Rev. J. V. Wilson, from his experience as chaplain to a mental hospital, spoke of the good results obtained from the joint efforts of doctors and clergy in bringing healing through the subconscious mind.

The new medical director of the hospital, who has lately taken up his duties, is Dr. Ford Robertson.

UNITED SHEFFIELD HOSPITALS

AT the annual meeting of this group of hospitals on May 12, Mr. A. Ballard, chairman of the board of governors, referred to the need for coöperation by the public. "At this meeting itself," he said, "we are hoping to attempt at least to induce citizens not to relegate all the problems of the day to a few people, or to take refuge in the illusion that the State o municipality is a separate institution from themselves, an that they no longer need play a part in raising our healt standards." The board had coördinated rather tha centralised. When the new service started the old administrative staff was retained almost without exception in the uni hospitals, and as far as possible the small staff of the centra office had been recruited from "transferred" staff. In othe words, no new bureaucracy had descended upon the hospita service. To foster coördination between the board o governors, the regional board, and the university, a liaiso committee, composed of representatives from each, had bee set up.

Discussing the position of the hospitals within the Nationa Health Service, Sir Ernest Rock Carling suggested that th problem of long waiting-lists was one to be solved not b boards but by the whole community. All the links in th health services must be welded into one chain—and link could not be thus welded without some disruption of thei atity. Waiting-lists for admission were long partly because discharge of patients already in hospital could not be anged. "In my opinion there is a need for 2000 homes this country, with 30-40 beds in each, where comfort ld be found by the elderly and infirm." The task of ucing the numbers seeking admission lay with the general-ctitioner service, which would be greatly assisted by lth centres.

MIDWIFE TEACHERS' TRAINING COLLEGE

A NATIONAL residential Midwife Teachers' College has been ened at High Coombe, Kingston Hill, Surrey. The first urse started on May 15. The new college will accommodate students for each six-month course. The students will y for their board and lodging and also a fee to cover the sts of tuition; but students employed within the National ealth Service may be seconded to the course on full pay. or many years instruction for the midwife teacher's diploma as been almost entirely on a part-time basis, and this has nposed a great strain on midwives. Two years ago, as an xperiment, two intensive residential courses, of four months ach, confined to theoretical instruction, were conducted by he Royal College of Midwives; the Central Midwives Board oncluded, however, that, to be of value, residential instruction or the diploma must be of somewhat longer duration and elated to practical midwifery and practical teaching. The iew venture is expected to meet this need. A council, made ip of representatives of the Royal College of Midwives, the Central Midwives Board, the Royal College of Obstetricians and Gynæcologists, the South West Metropolitan Regional Hospital Board, the Ministry of Health, and London University has been set up to administer the college.

MEDICAL SICKNESS SOCIETY

THE report for 1949 of the Medical Sickness, Annuity, and Life Assurance Society shows that during the year new sums assured under the life-assurance fund totalled £1,420,734, with an annual premium income of £46,557 and single premiums of £156. Purchase money for annuities amounted to £4300. The premium income amounted to £257,392, and the rate of interest earned on this fund was £2 18*s*. 11*d*. per £100 after deduction of tax. New sickness policies were issued insuring 9721 guineas per week with annual premiums of £21,857. £77,448 was paid in claims. The premium income amounted to £188,812, and the rate of interest earned on this fund was £2 18*s*. 3*d*. per £100 after deduction of tax. The total premium income increased to £446,225, and the expenses of administration amounted to £52,634—equivalent to 11·8% of the premium income. The total funds now amount to £4,371,026, the increase during the year being £329,060. Last year the society formed a subsidiary—the Medical Sickness Finance Corporation Ltd.—whose main object is to provide hire-purchase facilities for motor-cars and medical and dental equipment.

PATIENTS AT ALEXANDRA PALACE

THE television studios at Alexandra Palace last week resembled the meeting of a medical society, when patients were brought up to demonstrate points in a programme on radioactive isotopes in medicine, in the *Matters of Life and Death* series. The programme was introduced by Sir George Thomson, F.R.S., and Prof. W. V. Mayneord, D.SC., of the Royal Cancer Hospital; and others taking part were Prof. D. W. Smithers and Dr. Geoffrey Bourne. A normal person and a patient with hypoactivity and another with hyperactivity of the thyroid demonstrated the diagnostic use of radioactive iodine. The use of radioactive isotopes in determining the position of the placenta was shown on a pregnant woman, and a girl was televised being given an injection and having the rate of blood-flow in her leg measured. Prof. Le Bond supplied specially for the programme an autoradiograph, and the principle of radioactive isotopes was explained with the aid of diagrams. The programme was devised by Dr. Brian Stanford and produced by Andrew Miller Jones.

West London Hospital Medical School

On Wednesday, June 7, at 8.30 P.M., Sir James Learmonth will deliver the third Alex Simpson Smith lecture at the school. He has chosen as his subject the Surgery of the Sympathetic Nervous System.

University of London

Mr. J. B. Kinmonth has been appointed to the readership in surgery at St. Bartholomew's Hospital Medical College from June 1.

Mr. Kinmonth, who is a graduate of the University of London, qualified from St. Thomas's Hospital in 1938. After holding house-appointments there he served during the late war as a surgical specialist in the R.A.F.V.R. with the rank of wing-commander. In 1941 he took the F.R.C.S., and two years later his M.S. degree. With a research fellowship, he spent some time at Harvard University, and he was chief assistant in the surgical unit at Barts before taking up his present post of senior assistant in the surgical unit at St. Thomas's. He has published papers on thromboangiitis obliterans and on traumatic spasm.

In addition to those mentioned in our issue of May 13 (p. 935) Sir Alexander Fleming, F.R.S., and Dr. C. F. Harris have been appointed to the senate.

University of Manchester

On May 17, the honorary degree of D.SC. was conferred on Mr. V. E. Negus and on Lord Boyd-Orr, F.R.S.

University of Leeds

Dr. R. A. Willis has been appointed to the chair of pathology, from Oct. 1.

Dr. Willis, who is a graduate of medicine and science of the University of Melbourne, is at present director of the pathology department of the Royal Cancer Hospital, London. He has held the Collins chair of pathology at the Royal College of Surgeons of England. In 1942 he was elected F.R.C.P.

On May 19, the honorary degree of doctor of science was conferred on Dr. W. N. Pickles.

University of Sheffield

Dr. J. B. Parkin and Dr. B. A. E. Johns have been appointed demonstrators in anatomy, Dr. M. M. Platts research assistant in medicine, and Dr. J. C. Burne honorary part-time demonstrator in bacteriology. Dr. G. Ansell has been elected junior Graves research fellow.

Royal College of Surgeons of England

Prof. F. M. Burnet, F.R.S., will deliver the Moynihan lecture at the college, Lincoln's Inn Fields, London, W.C.2, on Monday, June 19, at 5 P.M. He is to speak on the Natural History of Surgical Infection.

Royal College of Surgeons of Edinburgh

At a meeting of the college held on May 17, with Mr. W. Quarry Wood, the president, in the chair, the following were admitted to the fellowship:

Kazi Shamsul Alam, A D. R. Batchelor, Binay Bhushan Bhattacharyya, A. L. De P. Carnegie, H. V. Corbett, A. S. Davidson, I. B. Faris, Fattouh Mohammed Fattouh, C. F. G. Fourie, E. F. B. Hamilton, A. P. Hayward, Narayan Laxman Kalle, James Lister, R. S. McCrea, A. G. O'Malley, R. G. Parker, I. R. Ross, L. M. Satchwell.

Conference of Surgeons of St. John Ambulance Brigade

A weekend conference was lately held at Harrogate, under the supervision of Mr. F. H. Edwards, the deputy surgeon-in-chief. Dr. Donald Towle spoke on Atomic Explosions and their effects on human beings with suggested lines of treatment. There were also papers on how the principles of child welfare and home nursing can best be taught to lay personnel, by Dr. Muriel Frazer (Belfast) and Dr. M. Maxwell Reekie (Manchester).

British Association of Physical Medicine

The association held its annual general meeting at the Royal College of Surgeons on May 12 with Lord Horder, the president, in the chair. After the meeting Dr. Frank Krusen, of the Mayo Clinic, read a paper on the work of the Bernard Baruch Committee in physical medicine and rehabilitation. Lord Horder also took the chair at the annual dinner, when the principal guests were the president of the Royal College of Physicians and Mrs. Russell Brain, the president of the Royal College of Surgeons and Lady Wakeley, Dr. Krusen, Dr. Svend Clemmesen (Copenhagen), and Dr. Martin Ott (Zürich). It was announced at the dinner that an International Association of Physical Medicine had been formed, of which Dr. Krusen had been elected interim president and Dr. Philippe Bauwens interim secretary.

A course of lectures suitable for candidates preparing for part II of the diploma in physical medicine will be held at 5 P.M., on Tuesdays and Thursdays from June 1 to July 4. Further details can be had from the honorary secretary of the British Association of Physical Medicine, 45, Lincoln's Inn Fields, London, W.C.2.

Nutrition Society

This society is to hold its annual general meeting and open scientific meeting at the London School of Hygiene, Keppel Street, W.C.1, on Saturday, May 27, at 10.30 A.M.

Society for General Microbiology

Prof. J. W. McLeod, M.B., F.R.S., has been elected president of the society for the session 1950–51.

First-aid and Home Nursing Course

A two-week course on first-aid and home nursing will be held under the auspices of the St. John Ambulance Brigade at St. John House, 15, Collingham Gardens, London, S.W.5, beginning on Sept. 2. Further particulars may be had from the warden.

National Council for Civil Liberties

The council is holding a delegate conference on Saturday, June 10, at the Beaver Hall, London, E.C.4, when psychiatrists, lawyers, and social workers will present evidence on the present working of the Mental Deficiency Laws and the need for reform. Further information may be had from the secretary of the council, 46, Westbourne Grove, W.2.

Course for General Practitioners

From July 3 to 8 a postgraduate course for general practitioners is to be held at the National Temperance Hospital, Hampstead Road, London, N.W.1. No subject matter has been included in the course which cannot be applied by the doctor in his own surgery using his normal equipment. Half the lectures are non-technical and aim at showing the doctor how he may best use the medical and social services. Applications for places should be sent to the secretary of the British Postgraduate Medical Federation, 3, Gordon Square, W.C.1.

Oxford Graduates' Medical Club

The summer dinner of the club will take place at Brasenose College, Oxford, on Friday, June 30, at 8 P.M. The chair will be taken by Sir Henry Tidy. All men who are Oxford graduates, studying or practising medicine, are eligible for membership. As accommodation is restricted, it will be impossible to allow guests on this occasion. Application for tickets (30*s.*) should be made as soon as possible, and not later than June 9, to the hon. secretary, Mr. E. G. Tuckwell, 73, Harley Street, W.1.

Horse Shoe Club

At 5 p.m. on Thursday, June 15, at 11, Chandos Street, London, W.1, a meeting will be held to consider the future activities of this club. Dr. Geoffrey Bourne will be in the chair. The club was started in 1932 to promote the exchange of doctors between the U.S.A. and this country and to give American doctors hospitality on their arrival here. It is hoped that former members and others interested in these objects, especially those who have lately visited the U.S.A., will attend.

On May 13, Baron Cornelius Ver Heyden de Lancey, M.D., D.D.S., LL.B., barrister-at-law of the Middle Temple and Gray's Inn, was sworn in as advocate of the Royal Court, Jersey, Channel Islands.

Appointments

Baxter, J., M.B., D.P.H.: tuberculosis M.O., Wallasey area.
Burgess, C. T. A., M.B.E., M.A., M.B. Camb., F.R.C.S.: visiting consultant asst. general surgeon, Ormskirk hospitals group.
Pooley, Joan, M.B. Lond., D.C.H.: asst. county M.O., Essex.
White, R. M., M.B. Edin., D.P.H.: tuberculosis M.O., Warrington area.

Colonial Service:

Dill-Russell, P. W., M.R.C.S.: deputy director of medical services, Nyasaland.
Galea, G. C., M.D., B.SC. Malta: M.O., Nigeria.
Hardman, J. L., M.R.C.S.: M.O., Nyasaland.
Kellett, F. R. S., M.B. Calcutta: M.O., grade C, Trinidad.
Lewis, L. F. E., M.R.C.P.E., D.P.M.: M.O., grade A, Trinidad.
Ozimek, A. M., MED. DIP. Cracow: M.O., North Borneo.
Ross, A. D., M.B. Edin.: M.O., Somaliland Protectorate.
Slinger, L. A. P., O.B.E., M.A., M.B. Camb., D.P.H.: senior M..B, British Honduras.
Sperber, Karel, O.B.E., M.D. Prague, D.P.H.: M.O., Seychelles.
Sutherland, H. D., M.B. Belf.: senior M.O., Northern Rhodesia.

Diary of the Week

MAY 28 TO JUNE 3

Tuesday, 30th

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.1
5 P.M. Prof. G. W. Pickering: Benign and Malignant H tension.
ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2
5 P.M. Mr. F. S. Gorrill: Physiology of the Bone. (demonstration.)
INSTITUTE OF DERMATOLOGY, Lisle Street, W.C.2
5 P.M. Dr. H. J. Wallace: Erythemato-squamous Erupt
INSTITUTE OF OPHTHALMOLOGY, Judd Street, W.C.1
5.30 P.M. Mr. T. K. Lyle: Surgical Treatment of Squint.
EDINBURGH POST-GRADUATE BOARD FOR MEDICINE
5 P.M. (University New Buildings, Teviot Place.) Prof. J. Spence: Staphylococcal Infection in Childhood with s reference to Osteomyelitis.

Wednesday, 31st

INSTITUTE OF DERMATOLOGY
5 P.M. Dr. H. Haber: Histology.

Thursday, 1st

ROYAL COLLEGE OF PHYSICIANS
5 P.M. Dr. E. R. Cullinan: Diseases of the Liver. (First lecture.)
UNIVERSITY OF LONDON
5 P.M. (St. Mary's Hospital, W.2.) Prof. H. M. Evans (University of California): Hormones of the Anterior Hypophysis. (First lecture.)
INSTITUTE OF OPHTHALMOLOGY
5.30 P.M. Prof. Arnold Sorsby: Corneal Dystrophies.
INSTITUTE OF NEUROLOGY, National Hospital, Queen Square, W.C.1
5 P.M. Prof. J. Lhermitte (Paris): Specular Hallucinations.
ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, S.W.1
4.30 P.M. Dr. Desmond Curran: Psychiatry demonstration.
UNIVERSITY OF BIRMINGHAM
4 P.M. (Medical School.) Dr. Frances Baird: Hypothyroidism in Childhood. (Last Ingleby lecture.)
HONYMAN GILLESPIE LECTURE
5 P.M. (University New Buildings, Teviot Place, Edinburgh.) Prof. C. F. W. Illingworth: Acid Secretion of the Stomach.

Friday, 2nd

ROYAL COLLEGE OF PHYSICIANS
5 P.M. Prof. E. J. Wayne: Modern Antibiotics.
UNIVERSITY OF LONDON
5 P.M. (St. Mary's Hospital.) Professor Evans: Hormones of the Anterior Hypophysis. (Last lecture.)
MAIDA VALE HOSPITAL MEDICAL SCHOOL, W.9
5 P.M. Dr. Redvers Ironside: Clinical neurological demonstration.
HEBERDEN SOCIETY
5 P.M. (B.M.A. House, Tavistock Square, W.C.1.) Prof. Hans Selye: Rheumatic Diseases as Diseases of Adaptation. (Heberden oration.)

Saturday, 3rd

HEBERDEN SOCIETY
10 A.M. (B.M.A. House.) Professor Selye: Rheumatic Diseases as Diseases of Adaptation. (Heberden oration.)

Births, Marriages, and Deaths

BIRTHS

Bonner.—On May 18, the wife of Dr. G. D. Bonner—a daughter.
Brentnall.—On May 13, the wife of Dr. G. C. Brentnall—a daughter.
Caddy.—On May 19, in London, the wife of Dr. David Caddy—a daughter.
Collard.—On May 13, in London, the wife of Dr. P. J. Collard—a daughter.
Dearlove.—On May 13, the wife of Dr. Arthur Dearlove—a son.
Dick.—On May 18, at Kingswood, Surrey, the wife of Dr. H. P. Dick—a daughter.
Edwards.—On May 18, at Didsbury, the wife of Dr. J. Edwards—a son.
Evans.—On April 28, at Lusaka, Northern Rhodesia, the wife of Dr. A. J. Evans—a son.
Farquhar.—On May 13, the wife of Mr. J. B. Farquhar, F.R.C.S.—a daughter.
Harwood.—On May 11, at Carshalton, the wife of Dr. H. F. Harwood—a son.
Hunt.—On May 14, in London, the wife of Mr. Alan Hunt, F.R.C.S.—a daughter.
MacGregor.—On May 15, at Oxford, the wife of Dr. Malcolm MacGregor—a son.
Montagu.—On May 18, the wife of Dr. J. D. Montagu—a son.
Naughton.—On May 20, in Edinburgh, the wife of Dr. James Naughton—a son.
Shorvon.—On May 14, at Sutton, to Dr. Barbara Shorvon (née Bensusan-Butt), wife of Dr. H. J. Shorvon—a son.
Sidey.—On May 17, in London, the wife of Mr. Don Sidey, F.R.C.S.—a son.
Stephen.—On May 14, at Carshalton, the wife of Dr. Stuart Stephen—a daughter.
Tomlinson.—On May 16, at Preston, the wife of Dr. A. M. Tomlinson—a daughter.
Watts.—On May 14, in London, the wife of Dr. Peter Watts—a son.
Woolf.—On May 15, in Edinburgh, to Dr. Cecil Mary Drillien, wife of Dr. Barnet Woolf—a daughter.

DEATHS

Gordon.—On May 17, at Tranwell Wood, Morpeth, Northumberland, William Ingram Gordon, M.B. Aberd.
Greig.—On May 18, at Croydon, David Low Greig, M.R.C.S., D.M.R.E.
Salt.—On May 17, at Burton-on-Trent, Edmund Cecil Salt, B.A., M.B. Camb., aged 78.

PSYCHOSOMATIC MEDICINE

PROBLEMS OF A DUAL APPROACH*

RANYARD WEST

D.Phil. Oxfd, M.D. Lond., M.R.C.P., D.P.H.

Dichotomy of Psychosomatic Medicine

AFTER several years of endeavour it remains difficult reconcile the attitudes of practising physicians and rgeons on the one hand, and medical psychologists on e other, towards that branch of medicine which both rties have agreed to call "psychosomatic." Practi-oners of general medicine find their firmest scientific round in the laboratory and the post-mortem room. here the findings are tangible, easy to teach, and suitable r examination; and of their association with advanced rganic disease there is no doubt. In therapy the general hysician has his new specific remedies, sulphonamides nd antibiotics. From all this "reality" the once-onfident dissectors of the psyche have to recede into he mysteries of Freudian mechanism and Freudian nterpretation. From their recesses they all too seldom merge to show convincing correlations between emotion nd functional derangement, or demonstrate successfully he power of psychotherapy to heal ulcers and relieve nuscular spasm. Effective psychotherapy is still more f an art than a science, and its techniques and media re almost incomprehensible to a man trained in purely physical medicine, as all students initially are.

Those who deeply comprehend the media in which the psychiatrist has to work are few; but they set the philosophical tone of the faculty. This involves a philosophical approach to medicine as a whole which makes it hard indeed for the psychotherapist to communicate with his general colleagues to their mutual satisfaction. Also the divergence is often something of a strain to the patients they share: it may be unsettling to the young man with a duodenal ulcer to have his feeling of insecurity or injustice suddenly taken more seriously than his diet, or to the young woman with ulcerative colitis to find a doctor really interested in her emotional dependence upon her mother. Actually, it is often the patients rather than their doctors who succeed in adapting themselves to two conflicting philosophies of health and disease, being prepared on Tuesdays and Fridays to probe the memories of childhood in search of solutions, while on Mondays and Thursdays they will admit, with well-feigned enthusiasm, that the kaolin (or katechu) is really doing them good. Such is their divergence of philosophy that the Tuesday doctor regards the katechu as a sop of suggestion equally to the patient and his colleague, while the Thursday doctor probably holds an ulcerative colitis due to emotional dependence to be at once incomprehensible, incredible, and incurable.

Changing Concepts

It was not with such dichotomy in mind that people like Dr. James Halliday originally advanced the concept of "psychosomatic affection" with its wide claims for the psyche in causation and its emphatic demand that the soma be affected in the event. Dr. Halliday's definition of a psychosomatic affection is "a bodily disorder whose nature can be appreciated only when emotional disturbances . . . are investigated" (Halliday 1943). Such claims for the psyche, made as they are in respect of peptic ulcer, essential hypertension, migraine, asthma, hyperthyroidism, dysmenorrhœa, dermatitis, &c., are sometimes vaguely conceded in theory without any confidence being shown in them in practice. Perhaps what should really be done is to universalise the claim for the psyche in medicine; so that the physician not only becomes willing to look at every case as potentially one of "psychosomatic affection" but comes to *expect* that his patients will in fact present a problem at once of body and soul in every case. Then the diagnostic physician would always ask himself Dr. Halliday's three questions: "Why did the patient take ill when he did?"; "What sort of a man is it who has got this illness?"; and "Why is this particular organ or function affected?" Such questions set the feet of the inquirer upon the track of repressed emotion as a determinant of bodily change. Anyone can recognise the neurotic in whom faulty emotion is a presenting symptom. Among general physicians the question: "Why this flamboyant response?" is a more familiar one than "What hidden emotion may have determined these organic changes?" Once invited to do so, the analyst is ready to take up the hunt arising from the second question as well as the first. But it is for the general physician to flush the quarry.

To the further question "How do somatic changes occur as a result of psychogenic derangement of function?" there are few workers trained and ready to discover the answers. It is a question the answers to which are in themselves worth having and may in their discovery do much to create the shared philosophy which we seek. We need to know what physiological processes are upset, and how irrecoverably, by neurotic states that are so easily reinstated as undue fear of death, inescapable protest against injustice, irrepressible or perverted sexuality, and many severe responses to mildly adverse environments. The planning and execution of such important researches would be easier if more psychotherapists and psychopathologists were also practising experts in other branches of study such as clinical medicine, experimental medicine, and applied physiology.

There is still a further fundamental need—namely, to chart the normal mind. Behind the psychopathology of idiosyncrasy and of character-type there lies the little-explored territory of normal psychophysiology. In organic medicine we ceased to be content to recognise the signs of advanced cirrhosis of the liver, sclerosis of the kidney, or failure of the heart, when something became known of how the liver, the kidney, and the heart should behave in health. Equally we may expect to pass a psychological milestone when we can turn from the mere recognition of a phobia as a fantastic fear of father with repressed aggressiveness to being aware of how normal father-son relations are established and the ways in which infantile aggressiveness ought to be ventilated. We know that we are a long way from such a state of affairs: but those of us who are both psychologically and physiologically minded can at least remind ourselves where to look for normal emotions—namely, in healthy animals and men.

But how to define our normals? We cannot perhaps do better today than accept *instinctual satisfaction* as the goal of the normal mind. It is not easy to catalogue instincts: we note the fundamental urges of man as we become more clearly aware of his functions. Signs of each instinctive desire—of self-assertion, to be loved, to be protected, to protect, sex, life-urge, death-acceptance—we must learn to expect all these from the psyche, each in its place. For the present, much of our information about normal instinct must come from Freudian psychoanalytical teaching: eventually we may hope to correct some at least of its past emphases by the application of necessary coefficients. All deep emotional material obtained by analysis requires partial discounting because of its distortion not only in interpretation but as a result of a rapport which derives a contribution of unknown force and content from the mind of the analyst himself

---

* Substance of an opening address to the Royal Medico-Psychological Association at their meeting at Shrewsbury on May 18, 1949.

In trying to establish norms we shall also do well to have some acquaintance with philosophical thought. Denied analytical techniques, philosophers have nevertheless thought a great deal about human nature for a very long time, and they have already exposed a number of fallacies into which the unwary psychologist may easily stumble.

Dysfunction and Organic Change

Armed at last with knowledge about the normal mind, we may hope to set about describing the abnormal in terms of dysfunction. That there is a relation between failure of instinctual satisfaction and dysfunction of appropriate systems of the body already stands out strikingly in any good system of case-history taking. We note, for instance, how often frustration of self-expression—and particularly the expression of aggressiveness—is to be found in cases of bronchospasm. The asthmatic may be stifled with rage, though that is usually the last thing to appear upon the surface. Again, we find complexes concerning fear of death appearing in cardiac neuroses, particularly in palpitations with multiple extra-systoles, effort syndrome, and substernal discomfort (or "pseudo-angina" if we are still allowed that deceptive but alluring term !). Doubts and anxieties about physical security or the sinews of war are the frequent lot of patients with peptic ulceration. The anxiety of such people is often overt. Of 70 cases of duodenal ulceration in patients at a Ministry of Pensions hospital I found undue overt anxiety in 35 and undue hidden anxiety in 23. Judging by one or two heart-to-heart talks with each patient, the overtly anxious had become so predominantly in matters of security to life and limb (they were war cases), while the hidden anxiety concerned life and limb, financial and social security, disturbances to love-life, and doubts of self-valuation—all about equally.

Cardiology shows the variety and confusion of our present clinical attitudes to the psychosomatic problem as a whole. The "either or" attitude is common, one cardiologist writing (in 1949) that "more often than not the differentiation between the pain of ischæmic heart disease and that of psychosomatic (sic) origin can be confidently made on the history." Organic disease is here treated as something quite separate from illness due to emotion. It would surely be more correct to speak of organic and functional heart troubles as frequently occurring together in intricate and fluctuating proportions ? *Is not true angina a psychosomatic disease of purest type, a bodily disorder whose nature can be appreciated only when emotional disturbances are investigated ?* Its cause is obscure: we still know all too little about the mechanism of constriction of the coronary arteries. But true angina can be precipitated by anxious excitement so instantly, and in patients who can undertake such considerable physical exertion in the presence of a calm mind, that the explanation of coronary spasm seems more appropriate than any other. Emotionally induced attacks of substernal pain, typically "vice-like" or aching, or atypical pains in parasternal or left mammary regions (or even internal to the scapular angle behind) may go on for years, and the end, when it comes, be from coronary disease.

One such patient, a pensioner, suffered from attacks of parasternal ache while on leave from minesweeping in 1942, and these continued to be excited by emotion, by mild exercise, or by the smell of new paint, until in 1947 he was found to have an abnormal electrocardiogram (widespread inverted T, with QIII present) and a day or two later he died of angina. Post-mortem evidence was of an old anterior coronary infarct, very narrow calcified coronary arteries, but no recent clot.

Such progress recalls "functional dyspepsia" with hypermotility and spasm preceding the organic ulcer. The mechanism in each case is a muscular spasm—its cause a bodily expression of emotion, mediated by nervous impulses and their chemical effectors, in what is *unconsciously* regarded by the patient as an appropriate organ. It may be easier to understand intestinal hypermotility in an animal anxious to recruit quickly for the coming fray than an emotion which leads to arrest of the heart. Slowing of the heart, or protection of its vessels, may be the primary purpose of the mechanisms involved. But cardiac neuroses cut deeply into character. The complexities of feeling of the human heart in respect of the death-acceptance instinct run very deep indeed.

Problems and Principles of Treatment

For purposes of therapy we have to regard psychosomatic affections in terms of the question "What functional derangement has to be undone ?" In so many of these affections there is, first, a hypertonus of plain muscle—bronchoconstriction, coronary spasm, vascular hypertension, hypermotility of stomach or duodenum, spastic colon. Inflammation and ulceration of endothelium or mucous membrane follow such "hyperkinetic" conditions, provided muscular spasm and ischæmia are maintained long enough. Ulcers which form quickly heal slowly and with scarring. All this has been demonstrated experimentally in the colon of the dog (Lium and Porter 1939) and its relation to the emotion of fear studied in the same animal (Drury et al. 1929). If deep emotional conflicts and fears can be countered with adequate reassurance at the stage of pure muscular spasm or early ulceration we may expect a psychosomatic dysfunction to be cured. In the case of ulcerative colitis the sort of psychotherapy which is sometimes necessary and adequate is indicated by the following case-history:

Miss A. B. suffered from ulcerative colitis from the age of 21 to 24. The picture was of periodic bouts of abdominal pain leading in the course of three or four days to the passage of mucus and blood with pyrexia. This caused her to give up an interesting but difficult secretarial appointment. The diagnosis was made by viewing multiple small ulcers at the pelvirectal junction two years after her symptoms started.

A psychological case-history was taken shortly afterwards. It yielded information at various levels. First it showed a personality in which considerable adult intellectual powers were confused and hampered by too passive and childlike acquiescence in almost total domination by a very stern mother. She did not trust her power of living an independent life. Withal she resented this domination and dependence and envied her carefree colleagues in the office. Secondly, behind this lay a combination of morbid desire and fearful repudiation of sex-feeling which appeared to be based upon unfortunate early experiences with a *reprehensible* grandfather and a naughty elder brother.

A reluctant admission of her emotional overdependence upon her mother made good the first stage of her treatment, reduced her symptoms, and increased her weight and confidence. It culminated in a triumphant but precarious independence when she left her home town amid maternal lamentations and maledictions. (Therapy time: 25 hours during 30 days in hospital.) Full rehabilitation required the elucidation of the deeper emotions described above, which only took some 10 more sessions of psychotherapy and which resulted in a much more normal attitude to herself and others. She completely lost her diarrhœa, mucus, and blood except during the tensions of her visits to her old home. A year later she was able to work in her home town and live regularly at home without any symptoms whatever beyond occasional emotional diarrhœa.

In general the intimate nature of the psychosomatic exchange is made plain to different degrees in different branches of medicine. The enterologist now seldom talks of "functional dyspepsia" as a thing apart from "organic dyspepsia": an ulcer calls him to more strenuous treatment but he knows the psyche to be involved in both. But bronchial asthma may be precipitated as a deadly disease so early in life, and has such striking physical components, that the general physician can hardly believe it to have more than a psychological "overlay." He is staggered when deep analysis cures an blished case. It has to be a very deep analysis, and hould all like it to be successful more often than it is. ypical situation in the psychotherapy of asthma is cated in the following letter from a lady of 35, had had asthma for 8 years, since the engagement ch preceded a "happy" marriage. (This marriage included sterility, dyspareunia, and intermittent idity.) One year after 40 scattered sessions of intense istorical anamnesis" in which much repressed childish ntment and aggressiveness had been ventilated, wrote:

> "Reflecting on the past 12 months I should say I have een 'very fair.' In August I had a shocking attack, nconscious 29 hours, oxygen and a week in hospital. hen the 'best ever' till November, when it started to o back to its old ways. I take as many tablets as ever. do consider the things we found had a bearing upon it: ringing them to light helped at the time, but only tem-orarily. The real cause is still repressed. There's no oubt it does take 200 hours! And in most cases it can't e done. . . . When the unconscious mind does surrender ts hidden clue it will be a fear of some kind."

Short of a full-dress and highly competent Freudian alysis, that is about all one now expects from psycho-rapy in a severe established asthmatic, despite the ntalising psychogenic suggestions that nearly always cur in the superficial presentation of the case. There e strong indications however that the answer is there r the finding. Both in research and in treatment thma is essentially a field for attack on a wide front, m excursions with anti-histamine drugs on the one nd to the fullest help our Freudian colleagues can ve us on the other.

It will be a healthy sign when such an asthma front ists; when, too, the cardiologist asks himself what nctional derangements pave the way—and at what age of the journey his patient now stands, and how retrievably committed—to the coronary ischæmia that tragically intervenes among the most energetic, ough often the least bucolically active, members of ciety; and when the clinical neurologist subscribes ore fully to the dictum of Sherrington: "In all those pes of organism in which the physical and the psychical exist, each of the two achieves its aim only by reason f a *contact utile* between them." Its aim and its failures, oth awaiting our further study.

There is still a plea to be made in the matter of sychosomatic teaching. The other half of the history f patients—the history of their emotional life in relation the symptoms complained of—must be taken if doctors re not to miss the clues which the psyche provides to the rigin of illness. It looks as if this can only happen if teach-g physicians incorporate psychological medicine into edicine as a whole and learn to take these histories hemselves, instead of leaving them to a specialist from department which is still too far separated from the eneral run of clinical thought and practice.

Acknowledgments are here made to the Director-General f Medical Services, Ministry of Pensions, for permission to efer to cases seen in a Ministry of Pensions hospital.

BUNDLE-BRANCH BLOCK

A second field in which the use of precordial leads has added materially to our understanding of the E.C.G. is that of bundle-branch block. Up to 1930 the common divergent type of curve was attributed to a lesion of the right bundle-branch, and the rare convergent curves were attributed to lesions of the left bundle-branch. The evidence on which this was based was as follows:

(1) Experimental section of the right bundle-branch is readily performed in the dog and sometimes produces complexes in which the main initial deflection is upwards in lead I and downwards in the axial lead (lead III or ano-œsophageal lead). This curve resembles common-type bundle-branch block in man.

(2) Anatomically in man and animals the right bundle-branch is a long slender delicate strand which does not divide and ramify till far down the interventricular septum. It was thought this rendered it vulnerable to destruction by even minute fibrotic lesions. The left bundle-branch breaks up almost at once into two main divisions which ramify immediately, and is apparently less easily severed by any except very extensive subendocardial scars.

(3) Lewis (1916) from studies of the rotation of the electrical axis during the course of ventricular systole, showed that in the common form of bundle-branch block the rotation was from right to left anticlockwise, corresponding closely to the rotation of the axis observed in the dog when the right bundle-branch was cut.

(4) Histological examination of serial sections from hearts which during life had yielded such curves showed that the lesion in common-type bundle-branch block was on the right side (Cohn and Lewis 1914, Mahaim 1928, Campbell 1929, Taussig 1929).

Oppenheimer and Pardee (1920) reported that in two cases they had found lesions on the side opposite to that predicted from the curves, and Oppenheimer and Oppenheimer (1930) published a further ten cases. Barker et al. (1930) demonstrated the form of extrasystoles produced by stimulating ventricles of the exposed human heart, and Wilson et al. (1932) suggested that in common-type bundle-branch block the right

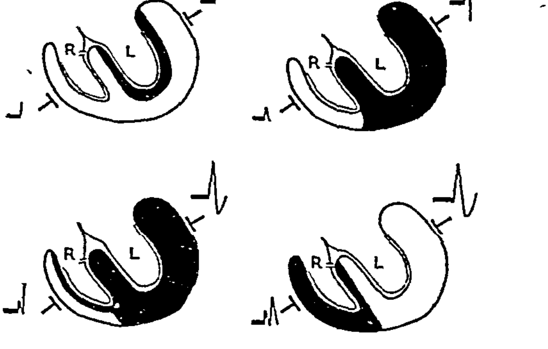

Fig. 15—Deformity of initial deflections in a direct lead from the ventricle after bundle-branch section and its causation.

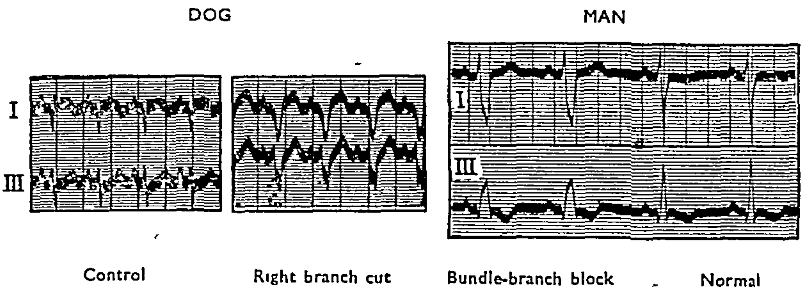

Fig. 16—Canine and human right bundle-branch block.

ventricle contracted first—i.e., that left bundle-branch block was present. Experimental studies on dog and cat were confirmatory. But the death-knell of the old concepts was sounded when the evidence from the new precordial leads was available.

Let us return for a moment to consider the E.C.G. by direct leads in normal hearts and in experimental right bundle-branch block (fig. 15). The form of initial deflections in such unipolar direct leads has already been described, and it is only necessary now to make clear that R is shorter and S deeper in leads from over the thin right ventricle, than in leads from the relatively thick left ventricle. When a bundle-branch is severed, the contralateral ventricle is activated normally, while that on the affected side lags inactive till the excitation wave reaches it from the muscle of the opposite ventricle. The lead from the normal side is of normal pattern in its early phases, though the prolongation of ventricular excitation as a whole prolongs the S or later part of the initial complex. The lead from the affected side, however, is grossly aberrant; it may or may not show small early waves, but the conspicuous feature is a late slurred R with a very much delayed intrinsic deflection. As we have seen, this intrinsic deflection signals the arrival of the excitation wave below the electrode, and its genesis is clear from the diagram (fig. 15).

The original experimental work in bundle-branch block was that of Eppinger and Rothberger (1910), who studied the well-marked E.C.G. changes that follow section of one or other branch of the A–V bundle in the dog. This work has been repeated by many workers and analysed in some detail by Rothberger and Winterberg (1913), Lewis (1916), and Wilson and Herrmann (1921). Briefly, section of either bundle-branch in the dog causes gross broadening and splintering of the initial deflections of the E.C.G. After section of the left bundle-branch the main initial deflection in all three standard leads is directed upwards: when the right bundle-branch is cut, the main deflection may be downwards in all three leads, or upwards in lead I and downwards in leads II and III, as stated above.

Wilson and Herrmann (1921), in a most ingenious experiment, showed precisely the mechanism of the production of such curves. In a dog in which the right bundle-branch had been cut they stimulated the right ventricle rhythmically by single break-induction shocks at a rate slightly higher than the spontaneous sinus rhythm. When the stimuli fell in ventricular systole or during the refractory period, the ventricular complexes were those of bundle-branch block; when a stimulus provoked an extra-systole, the resultant complex was practically opposite in form. But when a sinus beat transmitted through the intact left bundle-branch to the left ventricle coincided with a stimulus applied to the right ventricle, so that the chambers contracted synchronously, the resultant ventricular complex was of normal form as in the intact dog. This experiment showed not only that the normal E.C.G. is the resultant of summation of the two ventricular activations, but also that in right bundle-branch block the left ventricle contracts before the right.

Fig. 16 shows the result of cutting the right bundle-branch in a dog in which the right coronary artery had been ligated some days before. The gross change in form of the E.C.G. is apparent. In direct leads from points on the epicardial surface in such animal the leads from the contralate (left) ventricle are but little affected in their initial phases, whereas those from the side of the block are greatly deformed; the late intrinsic* deflection is noteworthy in these leads. Also shown in fig. 16 is an example from a patient in whom unstable bundle-branch block was repeatedly recorded. The general similarity of the changes between the two forms of complex to those produced by section of the bundle-branch in the dog is apparent.

Fig. 17—Electrocardiograms from a boy, aged 10 years, with inconstant right bundle-branch block.

(a) Standard leads. (b) Lead I with hot-wire sphygmograph of carotid pulse; in each record one complex is normal, the other shows branch block. (c) Electrocardiograms by two leads recorded simultaneously by two galvanometers; in each record the first complex is that of branch block, the second is normal. (d) Simultaneous records as above by various leads during the branch block, recorded on a fast plate. (e) As (d) during normal rhythm.

Note the late intrinsic deflection in right ventricular leads when branch block is present.

g. 17 shows curves from a boy, aged 10 years, with enital heart-disease, in whom the original tracings e on Aug. 31, 1937, show convergent rare-type dle-branch block.

om records made in the following two months it was ent that the block was not permanent but unstable. imes the curves could be made to revert to a more normal simply by deep respiration, and I secured tracings in h the transition was repeatedly recorded.

these experiments two galvanometers were used, making hronous records of lead I together with, at will, lead III, ght ventricular lead, or a left ventricular lead. It will een that there is relatively little difference in the earliest es of the QRS in lead C_4F, irrespective of whether I shows bundle-branch block or not. In the sternal C_2F from the right ventricular region there is, however, iderable difference between the QRS of the two rhythms. the fast plate the time from the beginning of R in lead I he intrinsic deflection in C_2F is about 0·05 sec. in normal hm and more than 0·1 sec. in the rhythm of the bundle-nch block. The delay in right ventricular activation is ifest, and the records are those of intermittent right dle-branch block. It is of interest, and corroboratory, the left ventricular ejection time, as gauged from a ultaneous record of lead I and a hot-wire sphygmograph tid-pulse tracing, is unaffected by the change of rhythm.

here are three main types of human curves which considered to indicate bundle-branch block. In h of these, slurred initial deflections and well-marked ay in the intrinsic deflection are evident in some but all of the precordial leads (fig. 18). In the common ergent pattern the right ventricular leads show small waves and early intrinsic deflections, whereas leads m over the left ventricle show gross delay in the ival of the excitation wave. The E.C.G. is therefore d as showing left bundle-branch block. It will noted that, in some cases when cardiac enlarge-nt is gross, it may be necessary to lead from points round in the left axilla before the electrode records e true left ventricular pattern. Conversely, in the e convergent block (fig. 17) delayed activation of the ht ventricle is apparent in the chest leads.

Wilson et al. (1934d) showed that another group of ses, whose standard leads till then had not been spected as belonging to bundle-branch block, yielded ecordial leads indicating right bundle-branch block. e standard-lead curves of this group vary consider-ly (Bayley 1934) but have in common a broad slurred S lead I. Today such curves are widely recognised, d the condition is known as Wilson-type right bundle-anch block. The incidence of ch curves is high; the convergent rves number about $^1/_{20}$ of the vergent, but the number of curves Wilson-type right bundle-branch ock is about the same as that of e divergent curves. The apparent sparity between the incidence of ght and left bundle-branch block s disappeared.

Another interesting point is the ear relation between the occur-nce of one or other type of bundle-ranch block and the incidence of rain on the corresponding ventricle -e.g., left bundle-branch block in ypertensive failure, and right undle-branch block either transient acute pulmonary embolism or ermanent in Lutembacher's syn-rome. The recognition of right undle-branch block is especially nportant since the diagnosis is till commonly missed, particularly no chest lead, or a single apical ad only, is recorded.

In addition to these three types of curves, however, one encounters now and then in clinical practice curves which do not conform to any of the classical patterns. Two examples are shown in fig. 19. In both of them the standard-lead curves show broad slurred initial deflections but in each the main initial deflection in all three standard leads is directed upward—i.e., is concordant as in left bundle-branch block in the dog. It will be seen from the precordial leads in these two cases that one is a case of left bundle-branch block and one of right bundle-branch block. The precise diagnosis rests on the evidence from the precordial leads; the limb leads alone are misleading. Similarly, downwardly directed concordant curves occur in which there is evidence of defective

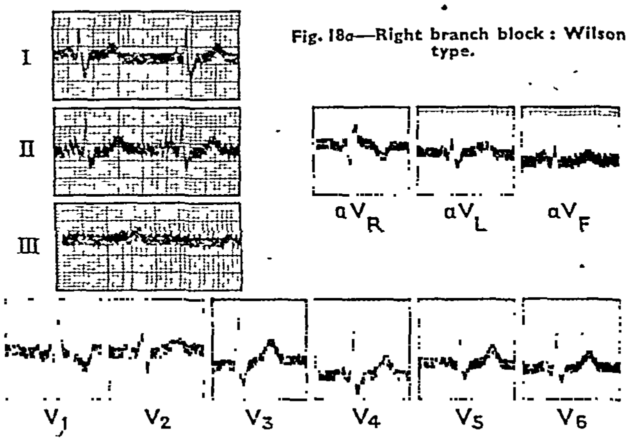

Fig. 18a—Right branch block: Wilson type.

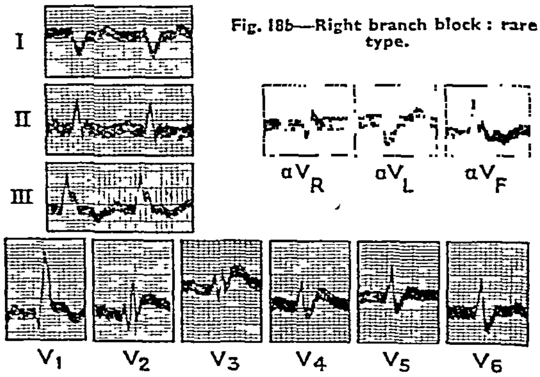

Fig. 18b—Right branch block: rare type.

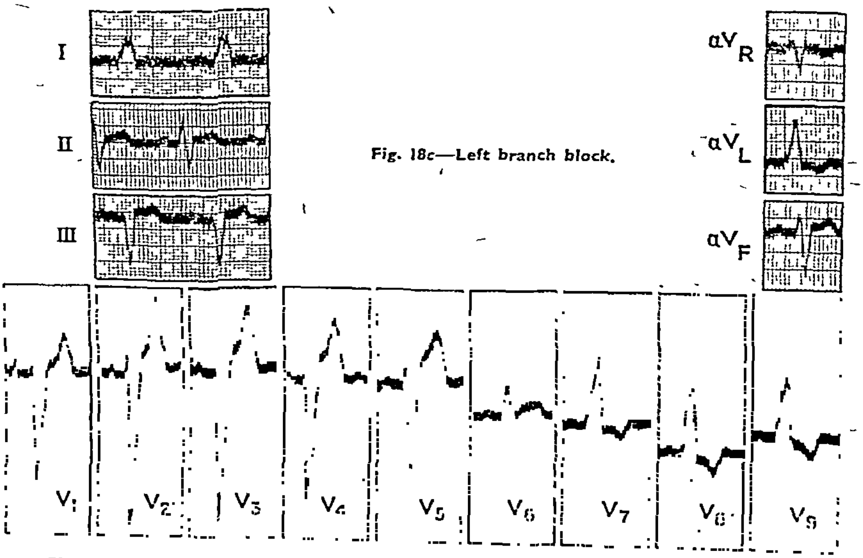

Fig. 18c—Left branch block.

Fig. 18—Clinical cases illustrating three classical types of bundle-branch block in man.

conduction through a bundle-branch. In some cases (fig. 20) there may be affection of both systems—e.g., a complete right bundle-branch transection and division of one of the main subdivisions of the left bundle-branch.

Bundle-branch block may occur in hearts the seat of recent infarction, or myocardial infarction may supervene in a heart the seat of bundle-branch block. In right bundle-branch block the combination of infarct curves and bundle-branch curves may be clear, but in left bundle-branch block the infarct curves are generally masked, a point of some importance. Infarction of the septum with bundle-branch block may cause bizarre records.

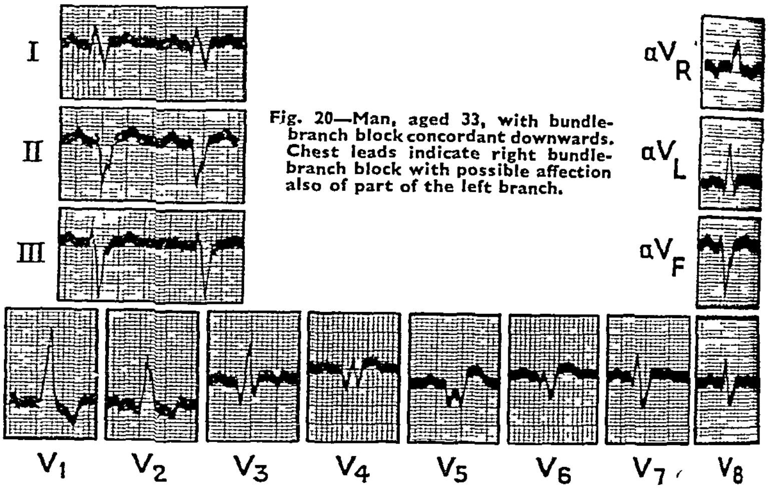

Fig. 20—Man, aged 33, with bundle-branch block concordant downwards. Chest leads indicate right bundle-branch block with possible affection also of part of the left branch.

It has been recorded that the standard-lead curve of left bundle-branch block may change form in striking manner, from divergent to convergent, without change in the precordial E.C.G. (Jones et al. 1949). Such changes can be produced by variation of posture in some people, and are then accompanied by conspicuous changes in the form of the unipolar limb leads.

VENTRICULAR HYPERTROPHY

From the early days of electrocardiography certain patterns in the standard-lead curves have been classed as evidence of right or left ventricular preponderance (Einthoven 1906, 1908), and Einthoven et al. (1913) introduced the concept of the electrical axis and the familiar triangle, so long a bugbear to students and a help to the experienced. Lewis (1925) still agreed that the familiar patterns of large RI and deep SIII and of large SI and tall RIII were the most reliable signs we possessed of preponderance of one or other ventricle in hypertrophied hearts (Lewis 1914, Krumbhaar and Jenks 1917, Herrmann and Wilson 1922, Wilson and Herrmann 1930). It has been recognised for many years, however, that the degree of ventricular hypertrophy found post mortem does not always parallel the classical signs of preponderance in the E.C.G. in life. Patients who had well-marked preponderance curves may show no hypertrophy post mortem, or gross hypertrophy may be found when the E.C.G. in life showed no axis shift. The observation that a pronounced left preponderance curve might swing over to normal during inspiration, only to reappear as the breath was exhaled, proved that the relative mass of the ventricular muscle was not the sole factor producing the curves, but that the position of the heart played a major rôle. From the Einthoven triangle it is easy to work out how a transverse heart yields an E.C.G. showing left ventricular preponderance, and a vertical heart a normal or right ventricular preponderance.

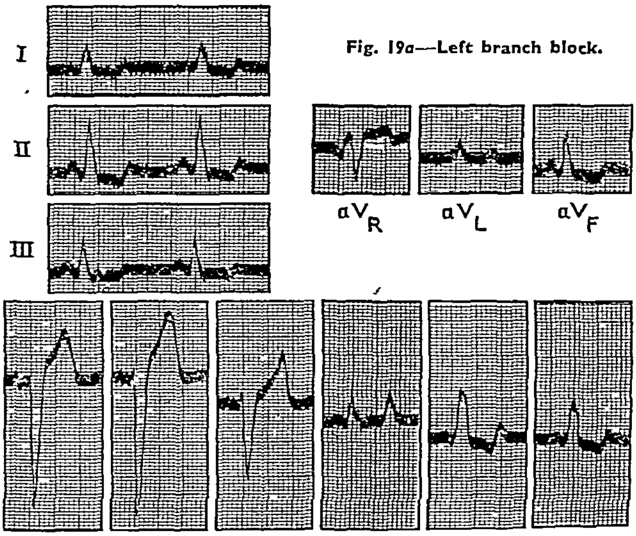

Fig. 19a—Left branch block.

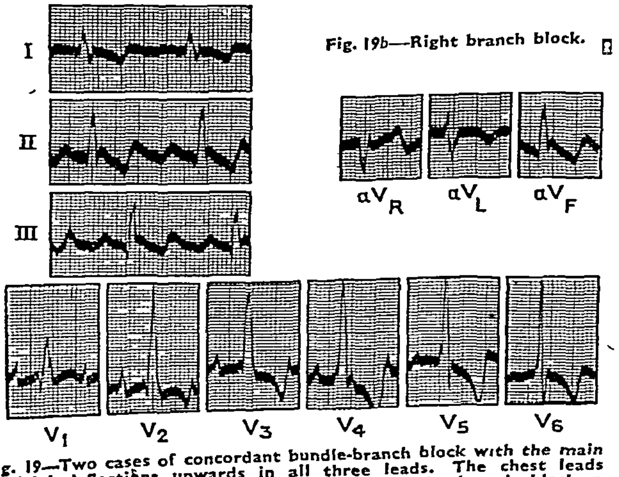

Fig. 19b—Right branch block.

Fig. 19—Two cases of concordant bundle-branch block with the main initial deflections upwards in all three leads. The chest leads indicate left branch block in case *a*, and right branch block in case *b*.

It has been recognised for many years also that, as ventricular hypertrophy progresses, secondary changes begin to appear in the standard-lead E.C.G., the ST segment becoming distorted and displaced from the iso-electric line, and the T waves possibly reversed in sign. It is the rule that such ST displacement is opposite to the sign of the main initial deflection in a given lead, and the T wave is opposed in sign to the Q R S. Thus, in advanced left ventricular preponderance ST is depressed and T inverted in lead I, RT elevated and T upright in lead III, whereas in gross right ventricular preponderance ST is elevated and T upright in lead I, and ST depressed and T inverted in lead III. Such curves have been called those of *left or right* “ ventricular strain ” by some workers—e.g., Katz (1946), a term to which there are grave objections. There is evidence that the ST shift and T reversal are mathematically related to the large initial deflection in the lead concerned, the total area of Q R ST summed algebraically remaining zero (Wilson et al. 1931).

There is now considerable evidence regarding the influence of ventricular hypertrophy on the form of the precordial E.C.G. In brief, leads from points over the hypertrophied ventricle show broadening of the Q R S as a whole, with very tall R waves and with or without a small preceding Q wave, and show ST depression and

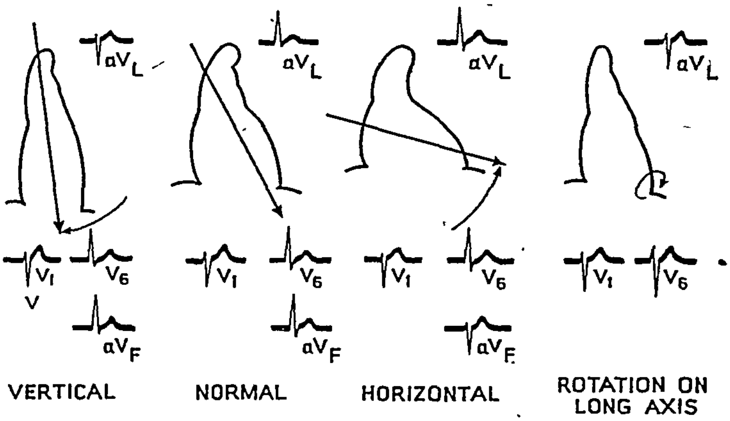

Fig. 22—Effects of cardiac rotation.

nversion of the type referred to above. The rinsic deflection or its equivalent (" intrinsi- d ") may be slightly delayed. The leads m the area over the other ventricle tend to ɔw unusually small R waves and deep S waves. amples from two clinical cases, one of vanced mitral stenosis and one of apparently complicated aortic stenosis, are shown in . 21. It will be noted that in the case of t ventricular hypertrophy the standard-lead rves show no axis shift, though ST and T anges are conspicuous.

The E.C.G. diagnosis of hypertrophy cannot divorced from consideration of the position the heart (Wilson 1943, Goldberger 1947, nes et al. 1949). As in bundle-branch block, e form of the standard-lead curves depends the form of the unipolar limb-lead curves, om pairs of which the standard-lead curves e derived. In fig. 22 the influence of rotation the heart about a horizontal anteroposterior axis shown diagrammatically. In the usual normal sition the left-arm and left-leg curves both resemble e leads from the left of the precordium, as though th these extremities "looked" at the left ventricle the lateral border of the heart. With clockwise tation to the vertical the left-arm lead comes to semble lead V_1 or V_2, while the left-leg lead remains left ventricular form. Conversely, with anti- ockwise rotation the left-arm lead remains of left entricular form, while the left-leg lead adopts the right entricular pattern. It is as though with the vertical eart the left arm looked at the conus of the right entricle, and with the horizontal heart the left leg oked at the right ventricle.

Rotation also occurs commonly along the long axis f the heart. In mitral stenosis, for example, right entricular hypertrophy is commonly associated with lockwise rotation, with the result that the conus comes bulge on the left margin of the cardiac shadow radio- gically. The influence of such rotation is indicated the diagram. Not only is the left-arm lead affected, but also the leads from the left precordium may come to be of right ventricular type with short R and deep S.

A third possible rotation is on a vertical axis, the cardiac apex being rotated forwards or backwards within the chest. Space forbids analysis of this complicating factor.

It is therefore clear that the standard-lead pattern in any given case depends on many factors, of which the degree of ventricular hypertrophy is only one.

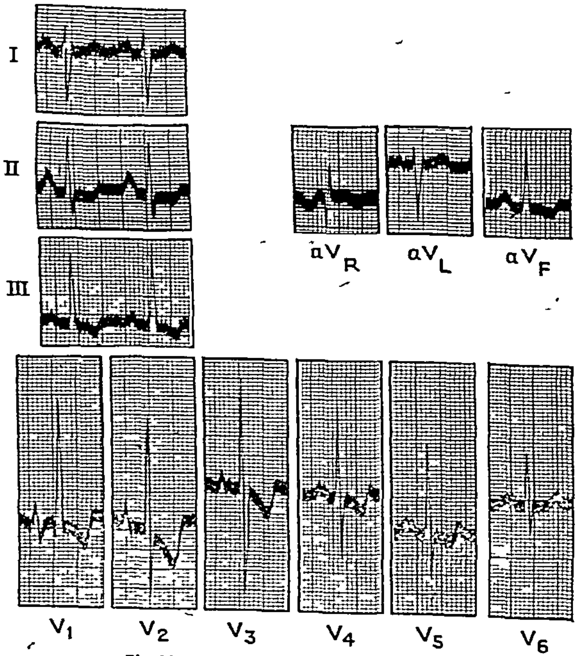

Fig. 21a—Right ventricular hypertrophy.

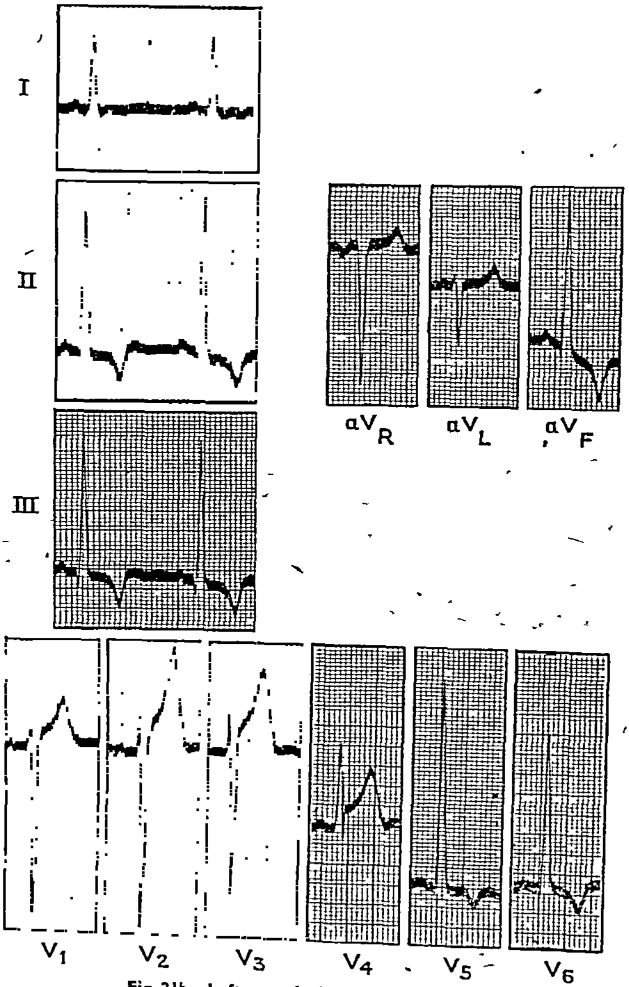

Fig. 21b—Left ventricular hypertrophy.

Fig. 21—Ventricular hypertrophy: *a*, in a case of mitral stenosis; *b*, in a case of aortic stenosis. Note the tall R waves with T-inversion in leads from over the hypertrophied ventricle.

In many cases the precordial leads clearly indicate hypertrophy of one or other ventricle. Examples are shown in figs. 23–25, the case of aortic stenosis without axis shift (fig. 24) being noteworthy. In the radiogram there is no generalised cardiac enlargement, though elongation of the outflow tract of the left ventricle is apparent. The standard-lead E.C.G. shows no axis-deviation, though ST depression and T inversion are gross. The precordial E.C.G. yields evidence of gross muscular hypertrophy of the left ventricle. Again in the case of right ventricular hypertrophy (fig. 25), the E.C.G. was of determining value:

A boy, aged 5 years, was subject to syncopal attacks associated with blanching and present intermittently from a very early age. Clinically he showed neither cyanosis nor clubbing and was ruddy, normally developed, and looked healthy. He had a small pulse and an enormous heart, with a gross basal systolic thrill and murmur transmitted widely up the great vessels. The second sound was present at the base. The oxygen saturation of the blood was over 97%, Hb 102% (Haldane). The initial diagnosis was subaortic stenosis. Radioscopy showed curious slow expansile pulsation *of the vascular pedicle, exactly like that of aortic stenosis* The E.C.G. was that of gross right-ventricular hypertrophy. The ultimate clinical diagnosis was pulmonic stenosis, probably infundibular, with poststenotic dilatation of the pulmonary artery. One day on his way to school the boy dropped dead. Necropsy showed gross valvular pulmonic stenosis with poststenotic dilatation, associated with an enormous right ventricle, vestigial left auricle, and very small left ventricle. No other valvular defect or shunt was present.

The striking transverse lie of the heart at post mortem was consistent with the E.C.G. pattern—the left-leg lead as V_1, the left-arm lead as V_2. It is important that the patterns of unipolar limb leads and precordial leads should be determined for each case, and generalisation from the so-called normal should not be allowed to influence the diagnosis of position.

Despite the striking patterns shown by the chest leads in many similar cases, often no evidence is obtained from precordial leads of ventricular hypertrophy in patien with severe hypertension, who might reasonably be expected to have such a condition. Perhaps the E.C.G. changes are due not to increase in muscle mass alone

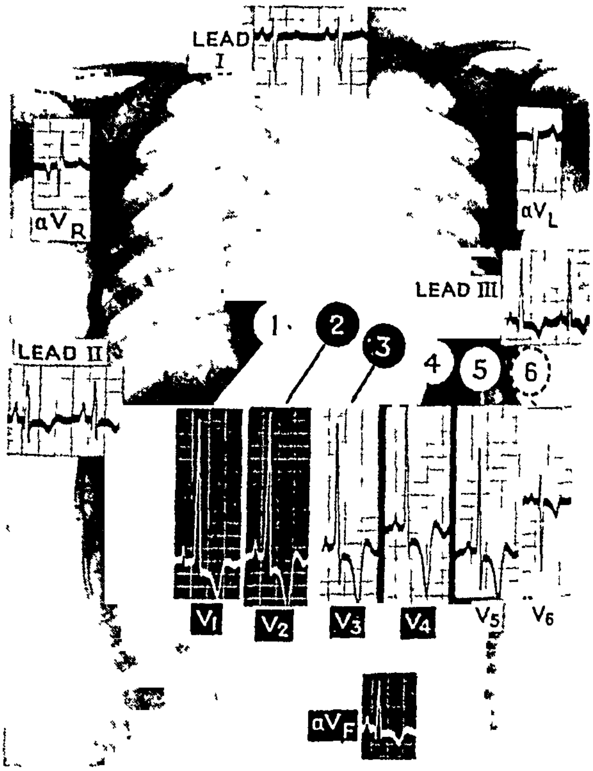

Fig. 25—Radiogram and cardiogram of a case of congenital pulmonary stenosis, confirmed by necropsy, with gross right ventricular hypertrophy and a rudimentary left ventricle. Mounted as in fig 23.

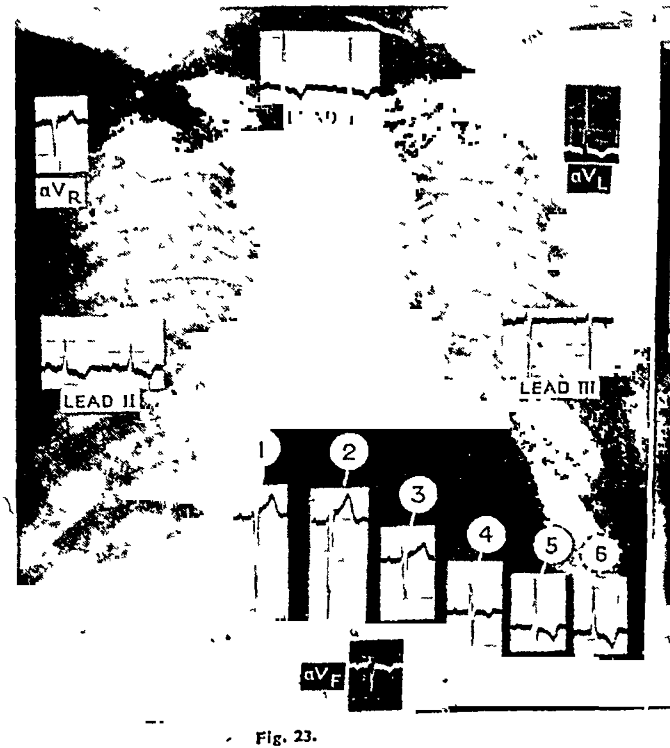

Fig. 23.

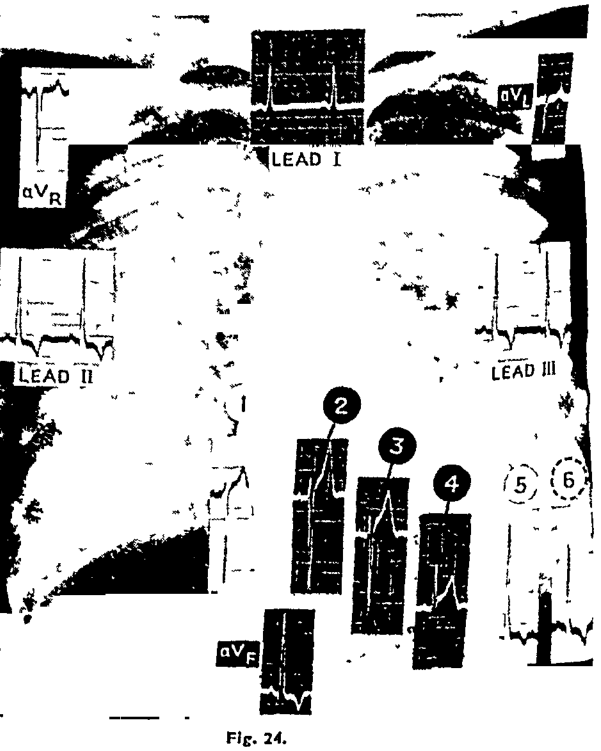

Fig. 24.

Fig. 23—Radiogram and cardiogram of a case of aortic incompetence. The cardiogram is mounted to show relations of the various leads. The unipolar limb leads are at the apices of a triangle, at right and left shoulders, and to the left of the xiphisternum. The standard leads I, II, and III are mounted between the limb leads composing, each standard curve; the chest leads are mounted serially below the positions of the chest electrode, indicated by white circles.

Fig. 24—Radiogram and cardiogram of a case of aortic stenosis mounted as in fig. 23.

t to some other factor secondary to the hypertrophy d only operative in long-standing cases—e.g., impaired od-supply to the fibres consequent on their great crease in diameter, making diffusion from the capillaries s efficient. Certainly the mere thickness of the uscular wall is not responsible for generating an creased voltage, for, as we have seen, direct measurement of the membrane potential of a single nerve-cell elds a value many times greater than the voltage of clinical E.C.G. The thick wall may lead to delay in the tivation of the layers of muscle farthest from the rkinje network, and this would lead to increased sitivity through the time factor. Slight delay in the pearance of the "intrinsicoid" deflection is in fact e of the criteria adopted by some workers for diagnosis hypertrophy curves (Myers et al. 1948a). It is well cognised that on occasion the borderline between ypertrophy curves and bundle-branch block can be ifficult to define. At present active research into the inical recognition and causation of the changes of the .C.G. in ventricular hypertrophy is being pursued in any centres (Kossman et al. 1948, Sokolow and Lyon 949, Myers et al. 1948a, Zuckermann et al. 1948).

CONCLUSIONS

I hope I have shown that the interpretation of cardio-rams today is by no means empirical or by rule-of-humb. There is a background of solid data derived rom animal experiment and corroborated in many nstances by observations on the exposed human heart nd even by leads taken from within its chambers. Rigorous pathological verification of clinical diagnosis as accompanied each step.

It must be emphasised, however, that the E.C.G. is nly one of the clinical bases on which diagnosis rests. The precision of diagnosis is evidence of the progress nade in detecting and defining the extent of lesions. The localisation of infarcts, for example, is clinically ot very important, but the ability so to pin-point their ite means precision in recording and interpretation. Yet some cases of coronary occlusion yield negative E.C.G., commonly in the early stages only, but sometimes throughout their course. As Cassidy (1946) says, the recognition of coronary disease is in the last resort a clinical diagnosis. In prognosis also the evidence of the E.C.G. must be interpreted with care. The E.C.G. shows certain features during the healing of an infarct which differ from those of relapse or recurrence, but in the average case tells us little or nothing about the prognosis. Again, most people with left bundle-branch block have a short expectation of life, but survival for many years is possible. The prognosis must be based on all the clinical data available, of which the E.C.G. is only a part.

For full understanding of the electrical phenomena, both of the individual cell and of the distribution within the body of potentials due to the heart, a considerable knowledge of physics is requisite. He who would penetrate the mysteries that enshroud the electrical phenomena of cellular activity must arm himself with a sharp mathematical probe (Hodgkin and Katz 1949, Wilson et al. 1933a and b). It is no fortuitous coincidence that the leaders of the new school of electrocardiography, like Einthoven, the father of this science, enjoy a mathematical facility which embarrasses the simple clinician. Those of us who lack either natural aptitude or training in this discipline, or both, must rest content with the hypotheses produced by the initiated, testing them rigorously by clinical observation and experiment, but incapable of entering into controversy over the solution of a differential equation here or the validity of a physical law there. The cry of the world is always for "practical men," and the dreamer and abstract researcher are little esteemed by their fellows; but it is to the pure research-worker, concerned with fundamental principles as opposed to applied science, that we owe in large measure the great advances of knowledge. So in electrocardiography our clinical superstructure today is built on the foundations laid by a few men, whose names have been repeatedly cited here.

ARTANE IN THE TREATMENT OF PARKINSONISM

BASIL K. ELLENBOGEN
M.D. Lpool, M.R.C.P.
SENIOR MEDICAL REGISTRAR, NEWSHAM GENERAL HOSPITAL, LIVERPOOL

BELLADONNA and its alkaloids have long been our mainstay in the treatment of parkinsonism, resisting the challenge of newer preparations. The latest of these is 'Artane' (Lederle Laboratories), trihexyphenidyl, or 3-(1-piperidyl)-1-phenyl-1-cyclohexyl-1-propanol hydrochloride, a potent antispasmodic now obtainable in this country. In America it has undergone extensive pharmacological trials and clinical tests in the past three years, with very favourable reports. In a study of 117 patients Doshay and Constable (1949) found artane to be an unusually mild drug resembling atropine in its control of sialorrhœa, cycloplegic effects, and cerebral stimulation, but free from the toxic effects of atropine on the cardiac vagus, blood-pressure, and circulation. It was remarkably free from disturbing side-reactions, it was not contra-indicated in the presence of hypertension or cardiac or renal disease, and no special precautions were necessary during its administration. Other favourable results have been reported by Corbin (1949a and b), who also found subjective improvement in spasmodic torticollis, facial spasm, and torsion spasm ; Dow and Rosenbaum (1949) ; Schwab and Tillmann (1949), who compared the effectiveness of artane alone and combined with 'Parpanit' and 'Benadryl' ; and Canelis et al. (1949), who noted more improvement than with atropine or hyoscine or a combination of the two, and remarked that patients did not develop tolerance to the drug, that the dose did not have to be increased to maintain its action, and that oculogyric crises were prevented or controlled.

In the present series twelve patients with parkinsonism were observed for 3–6 weeks : seven were of the postencephalitic, two of the senile, and two of the idiopathic group, and one was post-traumatic. In addition, the effect was noted on one patient with choreo-athetosis and one patient with hepatolenticular degeneration (Wilson's disease).

DOSAGE

The recommended dose is 8–10 mg. daily but varies with the patient, the senile and idiopathic type requiring smaller doses than the postencephalitic. In the present series the initial dose was 2·5 mg. (half a scored 5 mg. tablet), increasing by this amount each day to a total of 12·5 mg. in five doses. Where this amount was exceeded no greater improvement was obtained, and the patients developed side-reactions. For its effect on salivation the tablet was given before meals to the postencephalitic patients.

CASE-RECORDS

Case 1.—A male nurse, aged 42, had had postencephalitic parkinsonism for five years. There was no history of acute encephalitis. For more than six weeks he had been speechless. Atropine, parpanit, benadryl, and amphetamine had produced little or no effect.

On admission the patient lay motionless in a state of torpor for hours and had to be fed. He was moderately spastic but had no tremor. He was doubly incontinent.

Response to Artane.—Within forty-eight hours the patient spoke, recognised his family and friends, became alert, and moved about. He was less spastic and fed himself. He was still incontinent, but able to attend physiotherapy.

Case 2.—A man, aged 48, had had postencephalitic parkinsonism for thirteen years. There was no history of acute encephalitis. He had improved on parpanit, but treatment had lapsed. He was expressionless, apathetic, and immobile, and had bad days, when he could not swallow, drooled at the mouth, and had to be fed. He had oculogyric crises weekly.

Response to Artane.—He became alert, walking smartly with arm-swinging, fed himself, and no longer had bad da or oculogyric crises.

Case 3.—A woman, aged 43, had had acute encephalitis twenty years previously, after which postencephalitic parkinsonism had gradually developed. She was expressionless, had severe left-sided tremor, and constantly cried and complained of abdominal pain.

Response to Artane.—This was rapid. She became alert, walking smartly, with much reduced tremor. Abdominal pain was less, and the patient said she thought she had cancer. She cried less.

Case 4.—A woman, aged 35, had had sleeping sickness at the age of 11 years. Symptoms of parkinsonism had begun eleven years ago. There were now severe coarse tremor of the arms and legs, champing of the jaws, and moderate spasticity. The patient had sialorrhœa, oculogyric crises weekly, and could not feed herself.

Response to artane was immediate. The patient became alert, salivation was reduced, jaw champing ceased, and there was minimal tremor of left arm only. The patient fed herself, had no oculogyric crises, and helped in the ward. She had not felt so well since the onset of her illness.

Case 5.—A woman, aged 42, had had postencephalitic parkinsonism for three years, but had no history of acute encephalitis. She had slightly improved under treatment with stramonium and parpanit. She was expressionless and had severe tremor of the arms, very spastic legs, and indistinct speech.

Response to Artane.—Tremor was reduced, but spasticity unchanged. Speech was clearer. The patient could walk up and down stairs. Treatment was stopped inadvertently, and the patient relapsed in three days to her previous condition. She improved again on resuming artane, and asked to be allowed to continue with the drug.

Case 6.—A man, aged 50, had had acute encephalitis thirty years ago. Symptoms of parkinsonism had started fifteen years ago. He was expressionless, with a greasy face, and showed pill-rolling and tremor of both arms, and severely spastic arms and legs. He had oculogyric crises.

Response to Artane.—The patient felt 100% better. He was less spastic and could dress and undress himself and attend to his needs. He felt better on artane than he had on parpanit. Sweating was unchanged. The oculogyric crises ceased.

Case 7.—A man, aged 61, had had acute encephalitis in 1921, after which parkinsonism had gradually developed. He was obese and bedridden. He had a monotonous voice and tremor and spasticity of arms and legs. A good result had been obtained with parpanit, but the patient had been uncooperative.

Response to Artane.—The patient greatly improved, and said that artane was "better than hyoscine or belladonna." He could raise himself in bed and feed himself. His speech was clearer, his tremor had almost gone, and his spasticity was reduced.

Case 8.—A man, aged 45, had developed parkinsonism after a head injury in 1940. He had adopted an attitude of flexion, had a coarse tremor, mostly right-sided, and tremor of the head and tongue. He dragged his right leg and could not walk upstairs unaided or feed himself. He had obtained moderate relief from parpanit, belladonna, and benadryl.

Response to Artane.—The patient became alert, and his face regained expression. His spasticity and tremor were greatly reduced, and he stood upright, walking briskly, with his right leg not dragging. He fed himself and walked upstairs unaided.

Case 9.—A woman, aged 72, had had senile parkinsonism for ten years, with spasticity of legs, and tremor of left arm and leg. On artane she became more cheerful, with reduced tremor and spasticity, and felt less stiff.

Case 10.—A woman, aged 74, had had senile parkinsonism for two years. She showed a fixed expression, tremor and pill-rolling of her left hand, and spasticity of all limbs. Artane produced no change.

Case 11.—A woman, aged 67, had had idiopathic parkinsonism for three years. She was flexed and expressionless, with a moderate spasticity, no tremor, and shuffling gait. 'Rabellon' and parpanit improved her initially. Benadryl had no effect.

Response to Artane.—The patient became alert, with spasticity reduced, could undertake fine movements with her hands, and found it less effort to talk.

Case 12.—A man, aged 68, had had idiopathic parkinsonism r five years. He was expressionless, and had a monotonous oice. Rigidity and tremor were more marked on the left de.

Response to Artane.—Rigidity and tremor were much educed, and the patient walked better. His voice and xpression were unchanged.

Case 13.—A man, aged 60, had severe choreo-athetosis ollowing a bombing incident in 1941. His mentality was not mpaired. He could read, but fed himself with great difficulty and acrobatic skill. His speech was indistinct.

Response to Artane.—He temporarily improved, his speech ecame more distinct, and his movements, though of same requency and range, were less violent and more controlled. Feeding was less difficult. After a fortnight's treatment the patient's condition relapsed. No effect was obtained with 25 mg. of artane daily.

Case 14.—A man, aged 31, had hepatolenticular degeneration (Wilson's disease) which had been first noticed at the age of 18 months. He was mentally clear, humorous, and cheerful. His movements were violent and uncontrolled, partly a tremor and partly clonic movements of the limbs. His speech was indistinct and he had to be fed. Parpanit had had no effect.

Response to Artane.—Articulation became much more distinct, and tremor reduced. The patient could now be shaved, without his head having to be held steady, but he could not feed himself.

TOXIC REACTIONS

Like all antispasmodic drugs, artane leads to cerebral excitation, but it does not cause convulsions even with massive doses: it possesses half the mydriatic and an eighth of the antisialogogue potency of atropine, and its inhibitory effect on the vagus is only a hundredth of that of atropine (Doshay and Constable 1949). In laboratory animals no ill effects have been observed on the blood-pressure, respirations, blood-count, kidneys, liver, metabolism of sugar, growth, or reproductive organs. Artane is rapidly excreted without a tendency to accumulation (Corbin 1949b), and few toxic signs were seen during its trials in America. Side-reactions, less severe than with atropine, may be headache, giddiness, slight cycloplegia, and dryness of the mouth, but these may be avoided by giving a small initial dose and gradually increasing it (Schwab and Tillmann 1949). In the present cases two patients complained of temporary blurring of vision and one experienced nausea and amnesia for recent events when taking 12·5 mg. of artane daily which was relieved by reducing the dose without affecting the degree of improvement. Case 14 became talkative and restless and sang throughout the night. This condition cleared when the night dose was omitted. After taking 20 mg. daily for nine days he complained of dizziness, blurred vision, headache, and depression. This was prevented by reducing the dose to 12·5 mg. daily. Serious reactions reported in four cases by Corbin (1949b) were acute mental confusion, extreme agitation, and extreme dizziness and vomiting, and individual complaints were tinnitus, sore mouth, and increased diuresis. None of these were seen in the present cases. Examination of the blood weekly in all patients showed no decrease in the number of red cells, white cells, or platelets. There was no albuminuria.

DISCUSSION

The smallness of this series and the short period of observation allow preliminary observations only. These however, indicate that artane is a powerful remedy possessing the advantages of the belladonna alkaloids without their disadvantages. Removal of inertia, relaxation of spasm, and reduction in tremor are achieved, but not at the expense of dryness of the mouth and paralysis of accommodation. Nor is it necessary to increase the dose to the limit of tolerance to achieve the greatest benefit. Where artane is effective it is so immediately and dramatically. This must be seen to be appreciated. The patient becomes cheerful, alert, and more responsive. Thus, after the second dose, case 1 was roused as from a lengthy hibernation. Relaxation of rigidity and reduction in tremor lead to increased activity and independence. The previously helpless patient can dress and feed himself, climb stairs unaided, and walk erect, swinging the arms. An extreme example was case 4. On admission she was severely undernourished from inability to feed herself, with violent tremor. On the second day she fed herself comfortably, and after a week she was clearing away ward crockery without endangering it. Case 8 was similarly improved. Where there is much rigidity its relaxation may reveal a latent tremor (Corbin 1949a) or tremor may be aggravated (Schwab and Tillmann 1949). In this trial rigidity and tremor were equally affected, though other workers have found artane more effective against spasticity. It was more successful in the postencephalitic group, controlling oculogyric crises, than in the senile and idiopathic groups, and the improvement initially obtained in the patient with choreo-athetosis was not maintained.

Since we cannot cure but only relieve parkinsonism, and since artane does this effectively, it should be tried on a large scale so that its place in the treatment of the disease can be properly assessed.

SUMMARY

Artane, a new antispasmodic, has been tried in twelve cases of parkinsonism, one case of choreo-athetosis, and one case of hepatolenticular degeneration.

Initial results suggest that it is a drug of low toxicity and high potency in overcoming mental hebetude, relaxing spasm, and reducing tremor.

A large-scale trial is necessary to confirm these findings.

I am very grateful to Dr. R. P. Kemp, Dr. H. Fuld, and Dr. R. M. Evans, for permission to treat the patients admitted under their care.

In the past year we have been investigating the possibility of producing atrophy of the gastric glands by β-irradiation, and so reducing the secretory function of the stomach without affecting its function as a reservoir.

The idea arose from the work of Palmer and Templeton (1939), who treated duodenal-ulcer patients by irradiating the gastric fundus and body with X rays from the exterior. In a proportion of their patients they produced achlorhydria and hypochlorhydria, but the method had the disadvantage that adjacent structures (pancreas and liver) were also irradiated. It seemed to us possible to overcome this disadvantage by using an intragastric source of β rays, which would largely be absorbed in the gastric wall. The method has been tried experimentally in dogs, and our preliminary histological findings are presented here; in a later paper we shall report the results of studies on secretion.

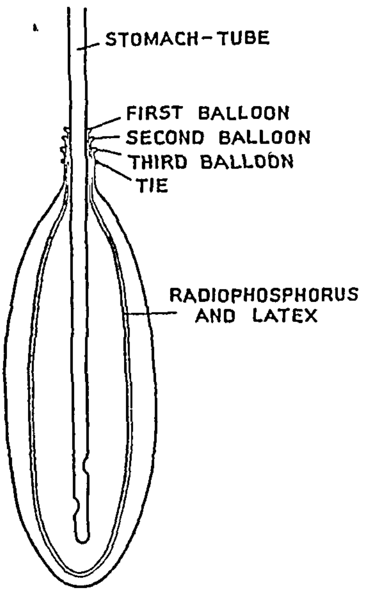

Fig. 1—Radioactive balloon assembly as intragastric source of β rays. P^{32}-latex layer is vulcanised between inner and middle balloons. When inner balloon is inflated, whole assembly assumes shape of stomach and lies in contact with mucosa.

METHOD

Source of β Rays

The intragastric source of β rays consisted of three balloons firmly attached to a 16 r. stomach-tube (fig. 1). Between the inner and middle balloons a mixture of 75 millicuries of P^{32} with latex was distributed as evenly as possible in the following way:

Manipulations were carried out in a chamber of $^1/_2$-inch 'Perspex' into whose sides lead-lined gloves were fixed (fig. 2). Monitoring showed that no β rays passed through this perspex. The inner balloon was passed over a glass test-tube large enough to hold it taut. The P^{32}, in the form of 1 ml. of phosphoric acid, was neutralised with $N/10$ sodium hydroxide and next mixed with 1 ml. of latex solution. The mixture was painted on the balloon as evenly as possible, the test-tube being constantly rotated in a stream of warm air. When all the P^{32}-latex mixture had been thus applied, the balloon was transferred to an oven, where it was vulcanised at 110°C for 15 minutes. It was next inverted, and the assembly was completed by passing a balloon inside it and covering it with a third balloon. The necks of three balloons were finally firmly cemented to the stomach-tube.

By this technique the radioactive material was made an integral part of the apparatus and could not escape into the stomach even if the balloon burst. This precaution is essential, since P^{32} is readily absorbed from the alimentary tract and, in the quantities used in this work, would cause widespread tissue damage and particularly rapid and severe anæmia.

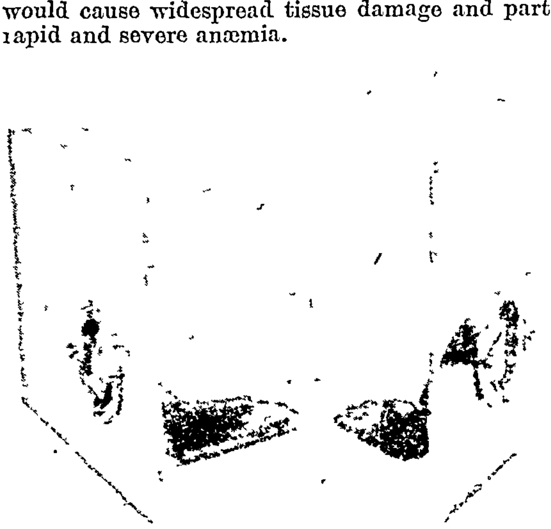

Fig. 2—Perspex chamber used in construction of radioactive balloon assembly. *Monitoring showed that no β rays penetrated the ½-inch perspex.*

Experimental Procedure

Four dogs were used throughout the study. They were trained to swallow a stomach-tube for the studies on secretion which will be subsequently reported.

For the introduction of the balloon assembly anæsthesia was induced with intravenous thiopentone and maintained with intratracheal ether. With suitable precautions the balloon assembly was passed into the stomach, and under radioscopic control it was gently inflated with barium emulsion to distend the stomach and to ensure that the balloon was in intimate contact with the mucosa (fig. 3). The balloon was left in position for periods ranging from 5 to 9 hours, depending on the extent of decay of the P^{32} and on the size of the stomach. From 39 to 74 days after the β-irradiation, biopsy specimens were taken from the stomach, and sections were stained with *hæmatoxylin and eosin.*

Fig. 3—X-ray film of radioactive balloon in position in stomach; *fundus* and antrum of stomach are well shown.

Dosage

The maximum penetration of P^{32} β rays in tissue is approximately 8 mm., but most of the biological action takes place in the first few millimetres. The problem of relating the dosage in this type of irradiation to that in normal X-ray therapy is still under consideration and as yet no accurate measurement in *röntgens* i possible. The dosage-rate was calculated approximately from the activity of the balloon and its surface area whe in the stomach. The time of irradiation was then adjuste to give an average dose of 5000r to the gastric mucos of each dog. Under these conditions the first few mill

The disease subsides by lysis in 1–2 weeks, though the patient may die, either in the acute stage or after a lingering illness. Deaths in 6 out of 9 cases (Sims and French 1948), and 4 out of 16 cases (McLachlan and Gillespie 1936) have been recorded. Highly infectious, the condition spreads rapidly among patients suffering from any form of skin disease.

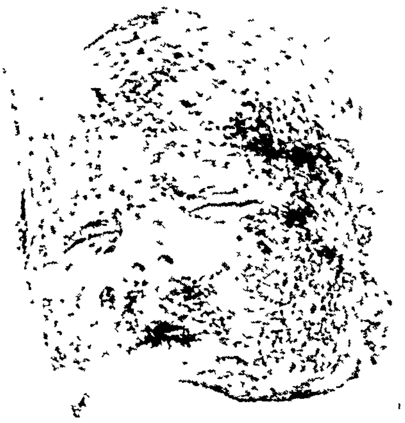

Fig. 2—Appearance of face at the height of the eruption.

Treatment, including sulphonamides and penicillin, has hitherto proved ineffective. The following case appeared to respond dramatically to 'Aureomycin' by mouth.

CASE-REPORT

A male infant, aged five months, was admitted to hospital on March 20, 1950, suffering from infantile eczema. The eruption had begun at the age of three weeks; and on admission the anterior half of the scalp and the forehead, cheeks, and chin were affected by a confluent oozing eczema. Patches of dry scaly eczema were found on the limbs and trunk.

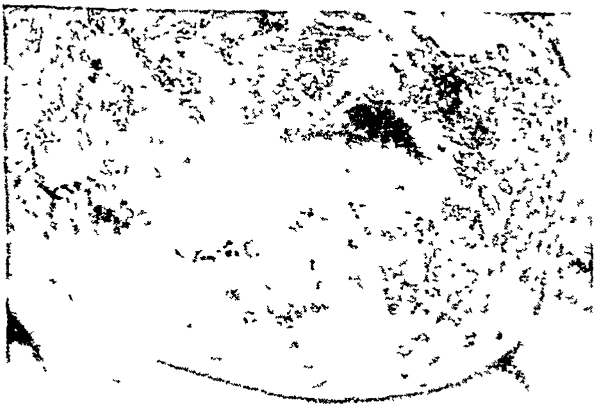

Fig. 3—The lower part of the face, showing labial ulcers.

The baby was well-developed, and there were no other abnormalities.

Treatment was begun with compresses of lead lotion to the moist areas, and oily calamine lotion to the dry. Progress was satisfactory for the first two days, but on March 23 the face was inflamed and swollen, and feeds were taken badly. Next day a profuse eruption of umbilicated pustules appeared on the left side of the head and face, and the baby was obviously ill. A diagnosis of Kaposi's varicelliform eruption was made, and treatment with aureomycin was instituted—250 mg. a day in four equal doses. Locally saline compresses were applied for twenty-four hours, and thereafter penicillin compresses—500 units per ml.

By next day the temperature had risen to 104°F (fig. 1); the eruption had spread to the chin and right cheek; and the left side of the face was raw and bleeding (fig. 2). The baby was semi-comatose, and small ulcers were found on the buccal and labial mucous membranes (fig. 3). In spite of this, feeds were taken well. There was obvious cervical and occipital lymphadenitis.

The condition altered little during the next two days, except that the pustules began to dry and scale and two fresh lesions appeared on the normal skin of the right index and middle fingers. On March 28, however, there was remarkable improvement. The temperature returned to normal, where it remained. No further pustulation occurred, and for the first time since March 24 the baby summoned up enough energy to cry while its dressings were being done. Recovery subsequently was uninterrupted, and except for two small areas in the occipital region, where there had been deep ulcers, no scarring resulted. Aureomycin was continued until April 3, since relapses occur in this condition. At no time was there any difficulty in giving the drug, and the baby only vomited once—on March 28, after the crisis.

Careful questioning of both the baby's parents and the hospital staff did not reveal any possible source of infection.

DISCUSSION

Kaposi's varicelliform eruption may take a mild and afebrile form. I can, however, find no report of a severe case with a high temperature spontaneously remitting by crisis after only four days of the disease. Control of the superadded staphylococcal infection by local penicillin is an unsatisfactory explanation for the sudden recovery in this case, since previous reports show that penicillin has no effect on the disorder. It seems, therefore, that aureomycin may have had a direct curative action, and its further use in this condition would appear justified. Unfortunately, although samples of blood and pustule fluid were obtained the day after the eruption appeared, it was not found possible to identify the virus.

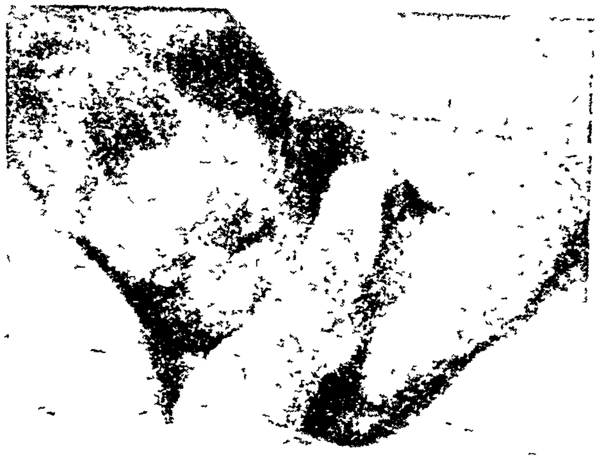
MEDICAL SUPERINTENDENT, INFECTIOUS DISEASES HOSPITAL, PORTSMOUTH

Generalised vaccinia is an uncommon but serious complication of vaccination and has a mortality-rate of 15–20%. About two-thirds of the cases occur in children with skin disease, especially eczema.

A boy, aged 6 years, was admitted to the children's ward in St. Mary's Hospital, Portsmouth, on Sept. 17, 1949, with acute pustular eczema of the face. His temperature was 102·8°F, and he complained of severe headache, was fretful, had severe anorexia and excessive thirst, and looked ill, as if the eczema had become secondarily infected. A swab from



Vaccinia resembling variola.

metres of the tissue would probably receive a dose of 20,000–25,000 r.

RESULTS

Histological Changes.—All four dogs showed atrophy of the tubular glands of the stomach, though in different degrees. The mucosa in dog 1 shows extreme atrophy (figs. 4 and 5), resembling that of achylia gastrica (fig. 6). There is a loss of almost all the tubular glands and an increase in the fibrous-tissue framework of the mucosa. In the absence of glands the intertubular prolongations of the muscularis mucosæ are prominent. Occasionally cystic spaces are present, lined by flattened degenerated epithelial cells. Similar though less marked changes are seen in the other animals (fig. 7).

No significant change is seen in the gastric submucosa or muscularis, but in dog 1 there is slight thickening of the vessel walls (fig. 4). The absence of fibrosis in the muscularis suggests that most of the β rays have been absorbed in the mucosa.

Epithelial-cell Counts.—A rough index of the loss of secreting epithelial cells was obtained by counting the number of those cells per high-power (× 600) field when the edge of the field was immediately adjacent to the muscularis mucosæ. For each slide four random fields were counted by two observers. The results, shown graphically in fig. 8, indicate the extreme atrophy in dog 1.

Health of the Dogs.—All the dogs are in good health, with normal food intake and satisfactory nutrition. Dog 1 lost weight for 6 weeks but has now regained it and is of average weight for its size and type.

DISCUSSION

Most forms of treatment for duodenal ulcer have as their aim a reduction in the free hydrochloric acid in the stomach. Though the basis of this is largely empirical, there is some evidence (James and Pickering 1949) that patients with duodenal ulcer secrete larger amounts of more acid juice at nights than do normal persons.

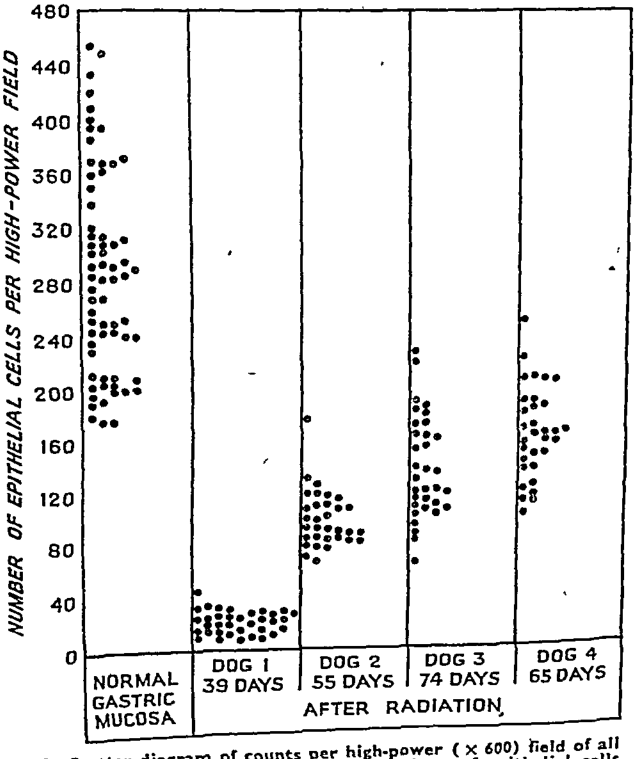


Fig. 8—Scatter diagram of counts per high-power (× 600) field of all epithelial cells. Normal control on left. Loss of epithelial cells after exposure to β rays is extreme in dog 1.

At the present time the operation of partial gastrectomy is the most effective method of producing a permanent reduction in gastric acidity, but this is not achieved without cost to the patient: The mortality is considerable (2–8%), the reservoir function of the stomach is lost, food capacity is poor and loss of weight common, and recurrent jejunal ulceration occurs in a small proportion (1–2%) of cases.

If the method described here will produce hypochlorhydria safely and consistently in animals, we hope that it will prove useful in the non-operative management of duodenal ulcer in man.

SUMMARY

The stomachs of dogs were exposed to β rays from an intragastric balloon in which was incorporated a layer of latex containing P^{32}.

Biopsy specimens of gastric mucosa were taken at intervals from 39 to 74 days after irradiation.

Various degrees of atrophy of the gastric glands were produced, and the underlying submucosa and muscularis were histologically normal.

We wish to thank the Tracer Elements Subcommittee of the Medical Research Council for the supply of P^{32}; and the North British Rubber Co. and the London Rubber Co. for technical advice.

KAPOSI'S VARICELLIFORM ERUPTION TREATED WITH AUREOMYCIN

P. Forbes Borrie
M.B. Camb., M.R.C.P.
ASSISTANT DERMATOLOGIST, WELLHOUSE HOSPITAL, BARNET

Kaposi's varicelliform eruption is a syndrome due to virus infection of skin already the site of eczema or dermatitis. The patient is usually a baby or a child suffering from infantile eczema, although adults may be affected. The virus may be: (*a*) that of herpes simplex, when the condition is called disseminated cutaneous herpes simplex; or (*b*) the vaccinia virus, the condition then being known as eczema vaccinatum. It is also possible that other viruses may cause the disease (Leverton and Whitlock 1949). In all cases, however, the clinical features are the same.

The onset is abrupt, with a high swinging temperature and severe toxæmia. At the same time a profuse eruption appears on the eczematous skin, consisting of vesicles which quickly become umbilicated pustules 2–4 mm. in diameter. Coalescence and rupture of these leaves a raw, bleeding, oozing patch. The process spreads rapidly, with severe inflammatory swelling, involving all the eczematous skin; and not infrequently pustules also appear on normal skin. Local lymphadenitis and gangrenous ulceration in pressure areas are other features.

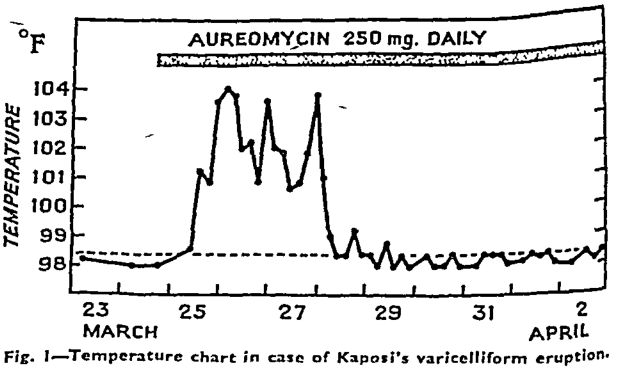

Fig. 1—Temperature chart in case of Kaposi's varicelliform eruption.

THE LANCET

LONDON: SATURDAY, JUNE 3, 1950

W.H.O.

THE World Health Organisation, whose third annual assembly has just been held at Geneva, has made an impressive start. One of the difficulties facing such a body is that in creating an international staff it must avoid taking too many from one country and must ensure the adequate representation of less highly developed countries. The need for members of the staff to adjust to the international atmosphere and to uproot themselves from their familiar patterns of life has engendered stresses in the young organisation. Nevertheless, an observer will be impressed by the spirit of enthusiasm of the staff, by the rapidity of expansion of the work, and by the evidence on all sides of friendliness and good human relations. The same friendliness and tolerance was to be seen among the delegates to the assembly; and if, at times, enthusiasm became damped, this might be ascribed to the enormous complication of the agenda and the long hours of work on detail. The assembly was faced with a number of unsolved political, administrative, and clinical problems. The communication of ideas and meaning is never easy in committee, but the obstacles are much increased when a large proportion of the delegates have imperfect command of either of the languages in use. Many misunderstandings and unduly long discussions would not have occurred had all delegates been perfectly at home in either English or French.

It could not be expected that W.H.O., which is composed of nations, would remain unaffected by political tensions. National delegations include lawyers and diplomats as well as doctors. Several national delegations appeared to be hampered by restrictive instructions from their own governments, and their consequent lack of powers of discretion tended to lower the standard of the discussions. The attitude of the Eastern European countries, which, with the exception of Yugoslavia, are at present abstaining from participation, could not be ignored. The very liberal constitution of W.H.O. makes no provision for resignation of a member State; but the continued absence, particularly, of nations holding a seat on the executive board confronted the assembly with a dilemma. Political influence could also be discerned in an unsuccessful proposal that individual members of the executive board should be directly responsible to their own governments, instead of to the organisation: in this proposal the politician was aiming at closer control. An opportunity to decrease this political influence in W.H.O. was, we feel, missed when the United Kingdom decided to stand for re-election to the executive board. The decision to stand down for a period would have set a precedent which could not have been ignored and which would have freed the board from any suggestion of subjection to power politics. The organisation awaits the emergence of a Great Power which will set such an example. In the more limited sphere of administration, the balance between doctors and lawyers was weighted in favour of the latter by the number of doctors who seemed to be thinking and acting as lawyers. Unfortunately there seemed to be some foundation for the comment made on various sides that the delegations of the British Commonwealth and of the United States of America were less helpful to the progress of the meeting than other delegations, being unduly occupied with points of order and procedure. On the other hand there was no evidence of voting in blocs or solid political groups, or of any carefully preconceived campaigns. From the standpoint of W.H.O., the value of the contributions made by national delegations varies directly with their readiness to act on behalf of the whole world, and inversely with their compulsion to follow their government's policy and consider the interests of their own nations. The spirit of international coöperation was perhaps most apparent in the Scandinavian and Latin delegations.

An excessive itemisation of the programme, lacking in qualitative discrimination, led during the discussion of concrete subjects, such as communicable diseases, to a kind of "arms race" among the countries particularly concerned, who wanted to raise expenditure regardless of the budget any limitations of the whole programme. Some delegates succumbed to the temptation to display special knowledge, and committees patiently endured many uninvited lectures. At times the programme committee, lost in discussion about individual diseases, lost sight of even health itself; at other times broad programmes of medicosocial amelioration received their justification in the somewhat unworthy terms of anticipated increase in industrial production, and the like. These programme difficulties can be overcome by improved preparation and greater experience of delegates, but this is a national matter on which W.H.O. can exert only a limited influence. It may be hoped, however, that time and growing experience will provide the solution to these incidental problems and thus leave the organisation free to tackle its proper job. Its approach to its task is far-seeing and broadly conceived, and its work is energetic and enthusiastic. There is ample good will, both among staff and delegations; the organisation is itself conducive to international harmony, which is more than can be said of all international agencies; and there is a growing realisation that the promotion of health is a world-wide concern. The absence, for political reasons, of certain nations is sincerely regretted and recognised as a source of weakness to W.H.O.; but the opportunities for work which remain are almost unlimited, and there is always the possibility that political influence in the sphere of health may abate and make coöperation possible in the future.

Recently medical readers have had the advantage of seeing a comprehensive review of W.H.O.'s work, published by the *British Medical Journal* in an "international health number" on May 6. Generally, however, this work receives little publicity, and the ordinary citizens of most countries know little or nothing about it. The reason is that the solid achievements of positive health work rarely make news, and that the only activities of the organisation which the pustules showed the presence of coagulase-positive *Staphylococcus aureus.*

Treatment and Progress.—Penicillin 50,000 units was given four-hourly, but the eczema gradually became worse, the pustules beginning to coalesce and weep. On Sept. 19, when the boy's temperature was 104°F, he was put on barrier nursing, and the dosage of penicillin was increased to 100,000 units four-hourly. On Sept. 21 the rash had spread all over the body and he was much worse, having severe toxæmia with delirium at times. One of us (I. M. M.) was then asked to say whether the case was one of smallpox or not.

The Rash (see figure).—A confluent pustular mass covered the face from the eyes to the chin, and there were a few scattered circular pustules on a slightly indurated base on the forehead. The scalp, mouth, and eyes were clear of lesions. A semi-confluent pustular rash covered the extensor surfaces of both forearms, and discrete lesions were present on the outer sides of both upper arms. The lesions on the extensor surfaces of the forearms much resembled variola, in that they were circular and umbilicated and had slightly indurated bases. These lesions extended along the backs of the hands to the fingers, but there were none on the palms. On the trunk were three or four circular umbilicated pustules scattered across the shoulders on the back and two on the chest but none on the abdomen. There were several similar lesions on the genitals, and on the legs the appearance and distribution of the lesions were similar to those on the arms. No lesions were found on the soles.

Diagnosis.—The diagnosis, which had to be made before it was possible to obtain a full history, was that this case was not one of variola, in spite of the similarity of the rash to that of variola. Crusts from the pustules, with scrapings from the bases of the pustules, were sent to Colindale Laboratory for bacteriological examination. Eczema vaccinatum was tentatively diagnosed.

Previous History.—Three hours later the boy's parents were interviewed. They said he had been subject to eczema since the age of 6 weeks and had recently been treated for it in hospital, both in Great Ormond Street, London, and in Portsmouth. He had been discharged from St. Mary's Hospital, Portsmouth, as recently as May, 1949. Both parents denied that he had been in contact with any recently vaccinated person; nor had the boy himself ever been vaccinated.

Course of Illness.—The patient was transferred to Crabwood Smallpox Hospital, Winchester, under the care of one of us (R. A. G.). Systemic treatment was begun with sulphadimidine and penicillin, and the lesions were treated with proflavine. In spite of tepid sponging the temperature remained at 103–105°F. Nothing abnormal was found in the blood. On Sept. 23 an interim report was received from Colindale Laboratory that the crusts and scrapings of the pustules were positive up to 1/64 (of 1/100 original) for vaccinia-variola in a complement-fixation test. The patient was given an injection of postvaccinal-encephalitis serum, but this seemed to have little effect. The pyrexia continued. On Sept. 25 signs of pneumonia appeared. During the night the boy's temperature rose to 107·2°F. Death took place the following afternoon.

Later inquiries showed that the boy had been playing in bed with a recently vaccinated infant still in an infectious state. A final report was received from Colindale Laboratory on Sept. 26 that egg-culture was positive for vaccinia.

We wish to thank Dr. Roderick Mackay, of Fareham, for the photograph and for obtaining the patient's previous history.

Reviews of Books

Postgraduate Gastroenterology

HENRY L. BOCKUS, M.D., professor of gastroenterology, University of Pennsylvania. Philadelphia and London: W. B. Saunders. 1950. Pp. 670. 50*s*.

PROFESSOR BOCKUS needs no introduction to those interested in gastro-enterology, and any book edited by him is certain of a welcome. Here are the printed proceedings of a postgraduate course in gastro-enterology given in December, 1948, under the aegis of the American College of Physicians. The volume covers many recent advances and includes symposia, panel discussions, and a few case presentations and clinical conferences. Twelve main topics are discussed by the 50 contributors, and the sections on gastric secretion, the œsophagus, and the pancreas are especially stimulating and provocative. Gastro-enterologists will find this an up-to-date appendix to the larger textbooks on the subject, but all physicians will be grateful for the full and balanced accounts of such things as vagotomy, gastric carcinoma, gastro-intestinal allergy, hepatitis, and non-specific enteritis.

Children of Today and Tomorrow

ETHEL DUKES; MARGARET HAY. London: Allen & Unwin. 1949. Pp. 249. 12*s*. 6*d*.

THIS popular book, inspired by high ideals, takes a middle-of-the-road common-sense position, from the standpoint that "spiritual values are absolutely essential in family relationships." So far, so good. But it does not seem to allow sufficiently for the good intentions of the human beings under discussion: e.g., "If only parents knew what harm can be done to their children physically, mentally and emotionally, by their stupid refusal to coöperate in marriages . . . ." Most parents, as a matter of statistical fact, *do* coöperate in marriage. Of the minority who fail to, many make superhuman efforts to endure the all but unendurable for the sake of their children. The authors do not point out that men, women, and children inevitably have defects in their characters, and that because of these they suffer and make one another suffer. In the second place they do less than justice to the psychotherapist, by underestimating the difficulty of his task. It is understandable that a book for general circulation should omit some of the more sordid details of mental disturbance: but surely the educated reader has by now ceased to regard sexual feelings and interests as sordid; and, surely, he has heard or is willing to hear that some extremely violent and unpleasant ideas actuate those whose overt behaviour is unacceptable? Parts II and III, however, give a good idea of how much can be done by superficial therapy and will be of interest to medical and social-science students who want to get some idea of what goes on in the play room of a child-guidance clinic.

Medical Diseases of the Kidney

An Atlas and Introduction. J. F. A. McMANUS, M.D., associate professor of pathology, Medical College of Alabama, Birmingham, Alabama. London: Henry Kimpton. 1950. Pp. 176. 42*s*.

THIS study, illustrated by 100 whole-page photomicrographs, is designed to bring the clinician and pathologist together over this difficult branch of medicine. The emphasis on the histology of the kidney, and particularly on the finer structure of the glomerulus, will be specially welcome to the many workers who are acquainted with Professor McManus's use of the periodic acid-Schiff stain for the demonstration of basement membranes. A section on normal histology is followed by others on acute and chronic renal disease, with special attention to the lesion of the crush syndrome, pyelonephritis, eclampsia, and diabetes mellitus, besides various forms of Bright's disease. Probably the illustrations, most of which are excellent, will be valued more than the text. But it is a pity that the magnifications of these are not given, and the stain used is seldom mentioned, though obviously for most it was periodic acid-Schiff stain. The text is unfortunately marred by many slips that suggest careless proof-reading, and is so loosely written that the meaning is not always clear. Nevertheless it is stimulating and provocative. The author believes that hyaline-droplet "degeneration" represents reabsorption of protein by the tubule-epithelium. But, if this is so, why is it so inconstant in proteinuria, and how does he account for the similar cytoplasmic change in other cells of the body? And many will question whether chronic pyelonephritis is the most prevalent of all renal diseases found at necropsy. Again, the statement that the larger renal arteries are normally of elastic type, like the aorta, cannot escape challenge and is belied by an illustration (fig. 25) which shows the usual muscular type. It seems that there is some confusion between elastic arteries and the "elastosis" of persistent hypertension. These criticisms, made in passing, do not alter the fact that this is a valuable contribution and a spur to further thought and investigation.

Patient	' Eosinophils per c.mm.		Change
	10 A.M.	2 P.M.	
Male 1	131	56	− 57%
Male 2	38	75	+ 99%
Female 1	363	106	− 71%
Female 2	213	350	+ 64%

It needs no elaborate calculation to see that these *normal* variations come within or exceed the range of changes regarded as of pathological significance.

The conclusion to be drawn from all this is that a reasonable figure for a patient's normal eosinophil-count cannot be obtained from a single count, or from several counts made at the same time. To minimise these spontaneous variations, **Rud** proposes that four counts should be made at fifteen-minute intervals in the afternoons of each of five or six successive days, and the average of these 20–24 counts will fairly represent the normal level. Even then the range of variation within the "normal" is large. For instance, he estimates 126 eosinophils per c.mm. as the mean count for absolutely normal persons. He then calculates that counts from 40 to 228 per c.mm. should be regarded as the normal range for males and 42–245 per c.mm. for females. In other words, at this level, reductions of less than 68% are not significant, and normal increases of up to 80% must be reckoned with. The only answer to this sort of variation is to perform *repeated* tests with A.C.T.H. as **Rud** does for normals. If, indeed, any reliance at all is to be placed on eosinophil-counts, not only must technique be first-class but a programme of repeated four-hourly A.C.T.H. tests must be undertaken if any useful estimate of adrenocortical function is to be made from the counts. No-one familiar with the inescapable variations of cell counting will be surprised that only big changes in eosinophil-counts are likely to be significant. That they should be so large as **Rud** affirms is unexpected but not improbable. It is clear that his results must be taken seriously and carefully examined before diagnostic significance is attached to variations in the eosinophil-count.

Substitutes for Curare

In the last few years curare has been accepted as one of the routine adjuncts to general anæsthesia for major surgery, first in Canada[1] and the U.S.A.,[2] and then, as supplies improved, in Britain[3] and elsewhere. An inevitable result has been a search for cheaper, and if possible better, synthetic substitutes. The broad principles relating chemical structure to curare-like action were familiar to pharmacologists long before **Griffith** drew the attention of anæsthetists to these muscle-relaxants, and many such substances had already been synthesised and investigated experimentally.[4] But the first synthetic substitute for curare to be given a wide clinical trial was 'Myanesin' or mephenesin, introduced[5] in 1947. This is a glycerol ether which produces relaxation of the skeletal muscles superficially resembling that of curare, but it acts at spinal-cord or basal-ganglia level, whereas curare neutralises the action of acetylcholine at the myoneural junctions; the action of mephenesin is therefore not reversed by neostigmine, the recognised antidote to curare. Unfortunately, the commercial preparations of mephenesin sometimes produced hæmoglobinuria through intravascular hæmolysis, and severe thrombophlebitis occasionally developed at the site of injection. After a good deal of controversy most anæsthetists have accepted the view that the risk of these side-effects is too serious for mephenesin to be used further in routine anæsthesia.

Then last year two other synthetic substitutes were introduced—'Flaxedil' or tri-(β-diethylaminoethoxy) benzene triethiodide,[6] and C10 or decamethonium iodide. Quantitative experiments on animals and on human volunteers have shown that flaxedil, in about five times the dosage, has an effect practically indistinguishable from that of *d*-tubocurarine and similarly reversed by neostigmine. So far the favourable reception of this drug by anæsthetists has been undisturbed by dissension. It has the advantage over curare of being readily miscible with thiopentone, so the two can be given in one syringe: it is also cheaper and has not the same tendency to induce bleeding. In recent reports on its clinical use, **Doughty**[7] has emphasised its value with thiopentone in preventing laryngeal spasm during intubation; and **Ruddell**[8] has described its use with intravenous pethidine and gas-and-oxygen as approaching the ideal combination for major surgery.

The position of C10 is less happy, mainly because no satisfactory antidote for it has yet been found. The first clinical report[9] noted that the antidote was not neostigmine but pentamethonium iodide (C5), another member of the methonium series. And later experience has proved that neostigmine or physostigmine, instead of counteracting the effects of C10, may increase its relaxant action.[10] Both pentamethonium and hexamethonium iodide (C5 and C6) have a potent blocking action on autonomic ganglia, like that of tetraethylammonium bromide (T.E.A.B.). In anæsthetised patients they produce a sharp fall in blood-pressure, which **Davison**[11] describes as "profound" and the manufacturers' leaflet as "precipitate"; while **Hewer** et al.[12] refer to the state of affairs as "an alarming degree of circulatory collapse." **Davison** has made the interesting suggestion that this fall in blood-pressure after the injection of C5, which may amount to 75%, could be made use of in surgery to obtain a bloodless field. However, such an effect will certainly be undesirable in a patient already suffering from paralysis of the respiratory muscles. Apart from the difficulty over an antidote, the efficiency in anæsthesia of any newcomer to the group of relaxants must be measured with the well-tried *d*-tubocurarine as yardstick, and it is not yet clear that C10 possesses any advantages over the natural drug. The muscular paralysis it causes usually lasts a shorter time than that of curare, but occasionally, for reasons not yet understood, recovery may be delayed, and the delay seems to be a real hazard. **Gray**[13] reports four such cases, in one of which muscular power did not return for are sure of commanding headlines in the newspapers are the repercussions of some political misfortune. Unhappily, this state of ignorance breeds apathy and enables the more chauvinistic elements of the press to attack W.H.O. on the ground that good money is being poured down an international drain with no hope of adequate return. In fact, however, the total expenditure of W.H.O. for the year 1951 is limited to 6,300,000 United States dollars (about £2 million); though the comparison is misleading, we may recall that this represents about 1/200th part of the cost of the National Health Service to Britain. Nobody would hold that the existence of an international organisation absolves member nations from their responsibility for the health of their own citizens, and the bulk of expenditure on health must be a national matter. Nevertheless health has many vitally important international ramifications which can only be dealt with by international action. Moreover, the progress of civilisation depends on the willingness and ability of more highly developed countries to bring aid to backward communities. W.H.O. is now empowered to spend money on international health work at the rate of only about one farthing per head of world population per year; and while expenditure remains at this level the world must be prepared to entertain only very modest hopes and expectations of what the organisation will achieve. All who can see beyond the boundaries of their own countries will be anxious to see it given a better chance to rise to the occasion.

The Significance of Eosinophil-counts

EOSINOPHIL-COUNTS have come into prominence lately because it has been found that administration of pituitary adrenocorticotropic hormone (A.C.T.H.) reduces the number of eosinophils in the peripheral blood. The A.C.T.H. acts by stimulating the adrenal cortex to secrete corticosterone; so, theoretically, the eosinopenia after giving A.C.T.H. could be used as an indicator of adrenocortical function. We recently[1] noted that a test on this basis has been proposed to detect patients who have poor adrenocortical reserves and would therefore be liable to surgical shock if submitted to operation, and also shocked patients who are likely to benefit from treatment with extracts of adrenal cortex. An obvious extension of this use of A.C.T.H. is the estimation of adrenocortical function in patients with endocrine disorders, and this subject has been reviewed by PRUNTY.[2]

In a normal person, A.C.T.H. increases the excretion of 17-ketosteroids and 11-oxysteroids, and increases uric acid excretion in relation to creatinine excretion; but reduction in the eosinophil-count is far and away easier and quicker to estimate than either of these effects. PRUNTY also estimates the ratio of uric acid to creatinine excretion, which is within the competence of most hospital biochemical departments. He describes two proposed methods of conducting the A.C.T.H. test. The first is the "four-hour A.C.T.H. test"; here a single intramuscular dose of 25 mg. of A.C.T.H. is given and estimations are carried out just before and four hours after the dose. In the "forty-eight hour A.C.T.H. test" 10 mg. of A.C.T.H. is given six-hourly, day and night, for forty-eight hours—making a total of 80 mg.; and the estimations are done just before the test and four hours after the last dose of A.C.T.H. The eosinophil-count in the four-hour test is the quickest way of obtaining the desired answer, and it could even be used in the outpatient clinic. PRUNTY gives figures to show that in the normal person there is a fall in the eosinophils of 50–98%, the average being 75%; in Addison's disease the range was from + 12% to − 8%; three patients with Simmonds's hypopituitarism gave + 24%, − 4% and − 17%, and four with chromophobe adenoma of the pituitary varied from − 15% to − 45%. These figures are thought to reflect the reduced adrenocortical function in Addison's and hypopituitary diseases.

Such a test as this, easy of application and economical in the scarce A.C.T.H., is designed for widespread application. But before it is put into practical use it would be as well to know the normal variations in eosinophil-counts. Fortunately this point has been exhaustively examined by FINN RUD[3] of Oslo. Since eosinophils are relatively few it is important to have a proper counting technique. All forms of "dry counting"—i.e., estimating the eosinophil percentage of the total leucocyte-count by examining dry stained smears or coverslip preparations—have proved in many hands hopelessly inaccurate for a purpose such as this. RUD therefore turned to the "wet" techniques, in which the eosinophils are counted directly in a hæmocytometer. Here the difficulty is to prepare a dilution fluid which will enable the eosinophil cells to be counted easily and to be clearly distinguished from other leucocytes, particularly neutrophil polymorphs. After experiment, RUD concluded that a solution containing magdala-red instead of eosin gave the best staining, and he, like DUNGER,[4] includes acetone to destroy the red cells. He used a large counting-chamber (the Fuchs-Rosenthal) and an ordinary white-cell pipette for giving a 1 : 20 dilution. Blood is obtained from a puncture, and according to LUCEY[5] the finger and not the ear should be used; if citrated venous blood is used, the count must be made quickly because the eosinophils tend to gather into clumps not dispersed by subsequent shaking.

The statistics of leucocyte counting in the hæmocytometer have often been worked out, and, having regard to the relatively small number of cells that will be counted even over the whole area of the large chamber used, changes of less than about ± 30% cannot be expected to be significant. But RUD's elaborate statistical analysis of a large mass of material shows that, in fact, the eosinophil-count of a normal person varies through an even wider range in the 24 hours and from day to day. During the day the *average* eosinophil-count rises in the morning and afternoon to a maximum in the evening, and then falls again; digestion, though traditionally blamed, has no influence on the variation. Unfortunately *individual* counts vary greatly and may go up or down during the day. The following figures, taken from RUD's table, show eosinophil-counts on normal persons taken at 10 A.M., and four hours later, at 2 P.M.

e treatment of peptic ulcer. So far Fitzgerald and ›hy have treated 62 cases with 15 g. of urea four to ; times daily, their object being to raise the blood- to 60–80 mg. per 100 ml. for periods up to six months. ing in mind that many of their cases had already ed refractory to other treatment, their results seem uraging, particularly in patients with anastomotic :s. But they add that the urea is unpalatable, ıent doses have to be taken, and the blood-urea levels t be watched.

MEDICINE IN 1850

r. Ashworth Underwood, curator of the Wellcome orical Museum, has got more rare and curious things how than he has space to show them. The museum ow housed at 28, Portman Square, London, in a se of charm and character ; but the galleries are not enough to allow of any large permanent display. He herefore arranging a series of small exhibitions, of ch that on the history of the microscope has now ı open for some time. However annoying this em may be for foreign doctors (who often arrive ious to see some special treasure of which they have rd, only to find it is not for the moment on view), it the merit of bringing various aspects of medical ory under detailed review, thus enabling the regular tor to study them more precisely and even enjoy ıe agreeable trifles which might otherwise never have ı the light. On May 30 a pleasing exhibition on ledicine in 1850 " was opened by Prof. Henry Sigerist, ose visit to this country is a momentous event for his fellow medical historians.

One of a curator's excitements is that of making expected finds among his own material. Dr. Underwood had the pleasure of discovering a hitherto undescribed trait of Liebig—a fine and lively piece of work— ned and dated by Wilhelm Trautschold. This, of ırse, has a place of honour in the new exhibition ; d a drawing, by the same artist, of Liebig's laboratory Giesson, in 1842, is also on view. The exhibition is anged under subjects, beginning with physics (one the original electrical piles made by Volta is there) d ranging through chemistry, biology, anatomy, ysiology, and pathology to medicine and surgery. One ing strikes home from many of the well-planned cases : w little importance we now attach to style and finish our equipment. Here are early microscope slides autifully mounted in scarlet and gilt paper ; shells and sects, prepared for microscopy on little ivory discs, attractive as the pieces of a mah-jongg set ; Galvani's sulator of twisted Venetian glass like a sugar-stick ; bber as it first reached us in the form of decorated ıgs or pouches to which wooden nozzles were fitted to ake syringes ; the endless varieties of early stethoscope, this wood or that wood, gracefully shaped, lovingly ›lished ; the beautiful teaching model of the ear and l its parts carved in ivory ; the elaborate papier-mâché rain which shows relations as no diagram could ever o ; and plate after lovely plate of coloured diagrams nd drawings—the infusoria from Ehrenberg's *Atlas*, ıe open pages of Cruveilhier's *Anatomie pathologique u Corps Humain* and Carswell's *Pathological Anatomy*, nd the engravings printed in colour which Richard Say id from Bright's own preparations.

To see these things is to long for the return of leisured raftsmanship. But the exhibition shows too how far ıodern technique has been able to carry some early ieces of ingenuity. Here are the first photomicrographs —daguerreotypes taken in 1844 by Léon Foucauld, orking with Alfred Donné. There was no known ıethod of reproducing the daguerreotypes, so engravings ere made from them, and published in 1845. Then there re the thermometers—shrinking from massive and bent orms to the first self-registering form, with an air-speck hich could be lost for ever by too resolute a shaking-down, and then to Clifford Allbutt's short thermometer, near kin to the modern type. The sphygmograph and the laryngoscope, too, have had interesting stories. Blood-transfusion, first tried in the 17th century, and demonstrated to Pepys and others at the Royal Society, slept forgotten for over a hundred years, and was revived in the early 19th century with a deal of apparatus : its history is well told here. The development of the hypodermic needle has its place too—and a teasing problem it was for those who had to solve it. This exhibition will have as much charm for laymen as for doctors, and fortunately it has been thrown open to them as well as to the profession. Until further notice it will be on view on every weekday, Saturdays included, from 10 A.M. to 5 P.M.

DELAYED EFFECTS OF RADIATION

It is a disquieting fact for the radiologist, and particularly for the radiotherapist, that doses of the ionising radiations sometimes give rise to long-delayed reactions which are usually serious. One could find no better illustration of the essential difference between the reactions of ordinary chemical or physical media and those of the living cell. Living structures do not react quantitatively to X rays and radium or neutrons, they react specifically ; when exposed to radiations they may seem completely unaffected, and yet in time, perhaps after several years, a reaction may appear. This is typified by the late reaction of the human lens reported in two different groups of ten people, the first being victims of the atom-bomb explosions in Japan,[1] and the second scientists working on the cyclotron.[2] Here the late reaction consisted in changes in the posterior cortex of the lens, tending in severe cases to produce complete opacity. In the first group the latent periods before visual symptoms appeared ranged from 6 months to $2^1/_2$ years. In the second group the severe effects (in 3 patients) did not develop fully until about 3 years after exposure to the radiation. These cyclotron workers had never been exposed to more than a " safe dose " of neutron and γ radiation, but it was continued for some years ; the cumulative doses they received were estimated at about 50n. Perhaps the nervous strain that these people were subjected to was a contributory factor.

Another kind of delayed effect may follow irradiation with radium or X rays for the control of uterine hæmorrhage if pregnancy occurs after this treatment. Giles[3] reported two such cases in which radium had been used before conception. In both of these the pregnancy ended in abortion, but Giles referred to the low abortion-rate claimed by D. P. Murphy in similar cases. Apparently no systematic study has yet been made of the children born of such parentage, but no-one would suppose that the considerable dose of radium commonly given for these uterine conditions could leave normal ovaries and uterus. Giles urged that if radium treatment is the method of choice the dose should be large enough to ensure an artificial menopause. Looking still further down the time-scale, H. J. Muller and Frank Ellis have both drawn attention to the danger that lies ahead for future generations if their forebears now living are unduly exposed to radiation ; for the gene mutations so caused may be passed down from generation to generation. This danger is limited by the fact that damaged genes are recessive, and a total dose of some 300r would be required to double the natural rate of spontaneous mutation. Few radiation workers are likely to receive more than 20r in ten years.[4] But men and women doing work which exposes them to larger doses should perhaps find their life partners in other professions.

several hours. It was perhaps a pity that C10 was put on the market soon after its first clinical tests. The anæsthetics committee of the Medical Research Council and Royal Society of Medicine had arranged for a large-scale clinical trial, but only an interim report[14] was published. Much more experience will be needed before its place in anæsthesia can be fully assessed.

Annotations

UNIVERSITY STUDENTS

If the science of human ecology is to justify its name, we may expect increasing attention to be paid to the relation between different groups within society, and in particular to the ways in which such groups become differentiated and maintain themselves. University students are a group of almost boundless interest to the sociologist, since they are highly diverse in both origin and destination, respecting neither social, economic, nor geographical boundaries; and yet within this diversity they show clearly some of the main trends of social development at the present time.

The Universities' Group of P.E.P.[15] have investigated the origins of students at six university institutions. The principal change in recent years has, of course, been in the direction of more equal representation at the university of students from different economic levels; but the stage which this process has reached varies widely between different universities. Information on this point was collected from four universities. According to the P.E.P. figures, the proportion of sons of manual workers rises from 7·7% at one of the two ancient universities (Camford) to 28·8% at a college of the University of Wales, with intermediate percentages at two modern English universities. For comparison, the proportion of manual workers in the employed population generally is given as 66·1%. Professional and administrative workers, who comprise 9·3% of the employed population, account for 66% of Camford students and 44·2%, 27·3%, and 25·8% of students at the other three institutions. Women students are found to come from slightly higher social and economic strata than the men. Educational statistics show a similar gradient, ranging from Camford, where 52% of the students come from fee-paying schools, to a college of the University of Wales with 6%. During the last twenty years the number of overseas students has risen only slightly, and their proportion has actually fallen. The most notable change is in the institutions they attend; the red-brick universities now attract their full share, and in consequence Oxford and Cambridge, London, and Edinburgh—traditional goals of Commonwealth and foreign students—take rather fewer than they did twenty years ago. United Kingdom students, it is found, have become more peripatetic; about 40% of men come from homes more than thirty miles away from the university—though this radius obviously has a very different significance in London and in Oxford or Cambridge (where the proportion is over 90%).

Most of the trends shown in this report conform with expectation. No more is claimed by the authors than that they are giving "some degree of statistical precision to what had been before only general impressions"; and they have been careful not to confuse testimony as to fact with political advocacy. The importance of this type of social accountancy is that it enables discussion of future policy to start from a basis of agreed knowledge.

CANCER OF THE UTERINE CERVIX

Cancer of the uterine cervix comes second to cancer of the breast as a cause of death in women, yet it is probably the most curable of the major cancers. It is often said that the first step towards better results is more prompt diagnosis by the general practitioner: but Harnett,[1] describing a five-year follow-up of 955 cases, shows that the patient herself, and not the doctor, is responsible for most of the delay. Only 45·5% of patients consulted their doctors within three months of noticing the first symptom, which was usually vaginal hæmorrhage; but 79·1% of all patients were referred to hospital at the time of their first visit to the doctor. Among 55 cases in stages I and II treated by Wertheim's hysterectomy the five-year survival-rate was 52·7%, while among 221 in stages I and II treated with radium alone the survival-rate was 40·7%. These samples, however, are not comparable. Of the cases treated surgically, 34 were in stage I and 21 in stage II (a ratio of roughly 3 to 2); while of those treated with radium alone 87 were in stage I and 134 in stage II—almost a reversal of the proportion. The survival-rate for all cases, treated by any method, was 27·7% at five years.

This account, which refers to cases seen in London hospitals during 1938 and 1939, may be compared with a report from Stockholm,[2] which shows that the crude survival-rate among 7675 cases of cancer of the cervix treated by radiotherapy in ten contributing hospitals between 1936 and 1941 was 37·8%. Clearly during the last twenty years radiotherapy has improved the prognosis of this form of cancer.

The Cancer Act of 1939 included provision for complete registration of cancer, one of the objects being the statistical comparison of methods of treatment. This part of the Act still stands, and one or two regions have started complete registration. Is it too much to ask that registration should now be extended to the whole country?

GASTRIC UREASE AND PEPTIC ULCER

The work of Fitzgerald and Murphy[3] on the distribution and function of the enzyme urease may throw some light on the pathology of peptic ulceration. This enzyme, which splits urea into ammonia and carbon dioxide, has been found in the gastric mucosa of several species of animals, and its concentration in the mucosa can be increased by feeding with extra protein or with urea. Fitzgerald and Murphy suggest that the ammonia formed by the urease may have an intramucosal neutralising action, thus protecting the stomach from digestion by its own acid. This idea seems to be supported by their finding the urease particularly in association with the acid-producing parietal cells. It was also present in the floor of an ulcer. Fitzgerald and Murphy demonstrated in man that raising the blood-urea by giving urea by mouth reduced the amount of acid and increased the amount of ammonia in the gastric contents after the injection of histamine; the amount of ammonium ion present did not completely cover the reduction in the amount of acid. Since the total chloride secreted did not fall, it is clear that they were dealing with neutralisation and not with suppression of secretion. The mechanism is a potentially powerful one, for the OH ions derived from 300 mg. of urea could neutralise 100 ml. of $N/10$ acid. Consideration of gastric blood-flow suggests that an arteriovenous difference in the concentration of urea of only 2–3 mg. per 100 ml. would supply enough urea to neutralise 100 ml. of $N/10$ acid per hour in man.

The neutralisation of gastric acid by gastric urease suggested that the administration of urea might be useful

[3] Fitzgerald, O., Murphy, P. *Lancet*, 1949, ii, 1108; *Irish J. med. Sci.* March, 1950, p. 97.

Last November. the council had postponed for six months lgment on *Eric Frederick St. John Lyburn*, registered as of Clinic (Tunbridge Wells) Ltd., Tunbridge Wells, M.B. Dubl. 30), against whom they found proved charges of advertising espect of the Lyburn Clinic, Tunbridge Wells. Dr. Lyburn ended and presented testimonials.

Mr. N. Leigh Taylor, for the complainants, the Medical fence Union, handed copies of the *Daily Telegraph*, for c. 8, 1949, containing, under the heading "Doctor Rejoins," report that Dr. Lyburn, speaking at Pembury, had announced that he was rejoining the National Health Service, d of the *Daily Mirror*, for Feb. 10, 1950, containing a otograph of Dr. Lyburn in an ultraviolet bath at his clinic, th an accompanying caption.

In reply to his counsel, Mr. E. M. Gorst, K.C., Dr. Lyburn d that the clinic was no longer called the Lyburn Clinic and name did not appear on the plate. He had made the nouncement at Pembury as a politician. He did not make appointment with the *Daily Mirror* photographer; he d the photographer to wait until he had had his treatment, t the photographer was in a hurry and suggested Dr. burn should be photographed in this way. Dr. Lyburn reed with Mr. Taylor that the press were usually present at litical meetings. Asked if he made the announcement of return to the service with the intention of arousing applause, . Lyburn replied: "I leave it to you. I spoke as a litician. I have a right to speak in Britain, Mr. Taylor; s not Russia."

The Legal Assessor asked whether Dr. Lyburn did not iow that the photograph was going to appear in the *Daily irror*. Dr. Lyburn said that many people sent for his otograph as a parliamentary candidate—the B.M.A. sent r it. The Legal Assessor: "What did you think was going happen to it?" Dr. Lyburn replied he did not know.

After consideration *in camera*, the President announced iat the Registrar had not been directed to erase Dr. Lyburn's ame from the Register. Dr. Lyburn then thanked the uncil and started to ask the council to support the idea of agnostic clinics; but he was stopped by the President, ho pointed out that he had already announced that the se was concluded.

Joseph Kevin Conlan, registered as of 81, Strubbington venue, North End, Portsmouth, M.B. Durh. (1940), appeared efore the council charged with having been fined at Durham 1948 on two counts of obtaining money by false pretence, her offences being taken into consideration, and of having een sentenced to six months' imprisonment at Portsmouth ty quarter session in July, 1949, for obtaining money with itent to defraud by falsely pretending that a cheque was a ood and valid order. The council at their sitting in ovember, 1949, had adjourned the inquiry.

Dr. Conlan said he had never had any intention to defraud. he first offences took place when he took to alcohol when eling depressed after treatment for illness. With regard to he second offences, he had no idea that there was not the oney in the bank; he had a joint account with his wife. e now took no alcohol, his health seemed very much better, nd he had obtained a post as an assistant.

The council found the convictions alleged against Dr. onlan proved and postponed judgment for two years, Dr. onlan to appear at the end of one year and produce estimonials.

John Matthew Campbell, registered as of Dromore, Omagh, o. Tyrone, M.B. N.U.I. (1942), had been found to have been onvicted of driving a motor-car whilst under the influence f drink or drugs; at the council's session in May, 1948, udgment was postponed for a year. In May, 1949, the ouncil postponed judgment further until November, 1949, ecause Dr. Campbell wrote stating that he was unable to ttend owing to indisposition and had been unable to produce estimonials because he had been at sea; and in November he council again postponed consideration of the case. At he present sitting Dr. Campbell did not attend. The Registrar was directed to erase his name from the Register.

NEW CASES

Stewart Quarterman Servanté, registered as of 7, West Road, ambridge, M.R.C.S. (1925), was charged with having been onvicted at Cambridge Assizes of procuring a miscarriage nd sentenced to 18 months' imprisonment. A letter was ead from the governor of the prison, stating that Servanté ad been informed of the council's letter and refused to attend. he council directed the Registrar to erase his name from the Register.

Peter Augustine Smyth, registered as of 33, Lillie Road, London, S.W.6, M.B. N.U.I. (1927), was charged with having been convicted and fined in 1947 for being under the influence of drink when in charge of a motor vehicle, and in 1949 for driving a car under the influence of drink or drugs and with driving in a dangerous manner. Dr. Smyth was present, and was represented by Mr. N. Richards, on behalf of the Medical Protection Society. The council found the convictions proved and postponed judgment for 12 months.

Garden Hepburn Swapp, D.S.O., registered as of 8, Bath Street, Stonehaven, Kincardineshire, M.B. Aberd. (1928), appeared charged with having been convicted and fined in 1945 and in March and September, 1949, for being in charge of a motor-car while under the influence of drink. The council found the convictions proved and postponed judgment for 12 months.

The council also postponed judgment for 12 months in the case of *Thomas Dunbar*, registered as of 63, Finlay Drive, Glasgow, M.B. Glasg. (1943), whom they found to have been convicted and fined in 1949 of driving a motor vehicle when under the influence of drink and without due care, and in 1950 of being in charge of a motor vehicle while under the influence of drink, for which he had been sentenced to a month's imprisonment and disqualified from holding or obtaining a licence for 30 years.

Council Business

Dr. J. P. Hedley presented the finance committee's report on the accounts of the General Medical Council and branch councils for 1949, which showed that expenditure exceeded income by £4000. Introducing the report of the public-health committees, Sir Andrew Davidson said there had been a continued fall in the numbers taking the certificates and diplomas in public health. Dr. H. Guy Dain asked whether this fall was a matter for concern. Sir Andrew replied that it was not possible to state its exact cause. After a war there was always an increase in the numbers of persons taking such courses. In the case of the certificate in public health there was a reduction of 58 out of a total of 240—roughly a quarter. In the diplomas there was a fall of about 80 out of about 240—roughly a third. At the moment the fall did not give cause for alarm. The fall last year was about the same as in 1948.

The President presented the report of the Pharmacopœia committee, containing the report from the British Pharmacopœia Commission. Prof. W. J. Dilling, he said, has been elected chairman of the committee. Sales of the *B.P. 1948* now total 37,770, and the Addendum, containing a number of new monographs and completely revised sections on antitoxins and vaccines, would be published later in the year. It was proposed to amend the requirements for sterile materials for injection so as to require that ampoules of injections should contain a definite excess over the actual dosage prescribed, this practice having been recognised by the Home Office. Consultation with the pharmacopœial authorities in the Dominions and the United States had continued, and the commission recommended that the provisions of the *International Pharmacopœia* to be published by the World Health Organisation should be adopted for the *British Pharmacopœia*, subject to a reservation about the right of introducing modifications in details.

Nine years ago, in the same German air-raid which destroyed the Queen's Hall, the house of the General Medical Council, 44, Hallam Street, London, which is also the headquarters of the Dental Board of the United Kingdom, was extensively damaged by fire. Now the damage is being repaired and other improvements made. Before the fire was put out it damaged, among other parts of the building, the rooms occupied by the British Pharmacopœia Commission as laboratories. The General Medical Council's building, which was specially constructed for its purpose, was opened in 1916; the Dental Board part was added later, in the same style.

In the council chamber the coat of arms of Sir Herbert Lightfoot Eason, president from 1939 until his death in 1949, has been added to the stained-glass arms and monograms of previous presidents in the window behind the President's chair.

(*To be concluded*)

GENERAL MEDICAL COUNCIL

SESSION MAY 23–27.

OPENING the 177th session of the council, Prof. DAVID CAMPBELL, the president, welcomed Sir Archibald Gray as representative of the University of London in succession to the late Sir Herbert Eason. He referred to the retirement from the Ministry of Health of Sir Wilson Jameson, who was a member of the council from 1942 to 1947, and said that, Sir Wilson "gave support of inestimable value to three causes, medical education as a whole, education in public health in particular, and the promotion of legislation by which these ends and the effective organisation of the council for their duties might be better secured. It is no secret that the emergence of a Medical Bill into practical politics, and the principles of many of its provisions, are due largely to his influence and persuasiveness."

In his address the President recapitulated the main provisions of this Bill, which, he said, "will, I trust, be read a third time and passed by the House of Lords, to be sent to the House of Commons, within the next hour." Under the Act of 1886 success in a qualifying examination had been made the primary condition of registration in the Medical Registrar; but experience had convinced those best able to form an opinion, including the Goodenough Committee who reported in 1944, that this is not now enough. It was therefore proposed to make a fundamental change in the conditions of registration of persons qualified in the British Islands by requiring them to render satisfactory service as house-officers, for a period to be laid down by regulations, before they can be fully registered as registered medical practitioners. Meantime they would be registered only provisionally.

> "Service in approved places may consist of employment either in medicine, in surgery, or in midwifery (or in posts involving the practice both of medicine and of surgery, or of all three subjects); or it may consist of employment in an approved health centre by a registered medical practitioner in the provision of general medical services, or in the provision of outpatient services.
>
> "The allocation of time between the alternative forms of employment, within the period of service as a whole, is to be determined by regulations of the council which fix a period or minimum period of employment in medicine or in surgery, and a period spent in midwifery which may be counted, at the option of the house-officer, as time spent in either of the other two subjects. The council may also fix by regulations the period of employment in a health centre which may be counted as time spent either in medicine or in surgery. Licensing bodies are to apportion the time spent in posts involving the practice both of medicine and of surgery, or of both subjects and midwifery as well.
>
> "We may, I understand, assume that the expressions 'medicine' and 'surgery,' as subjects in which posts may be held, include the branches of these subjects which are commonly referred to as specialties."
>
> "Provisional registration will put house-officers in the position of registered medical practitioners so far as is necessary for the purposes of their work, and will make them subject to professional discipline.
>
> "The requirement of satisfactory service after qualification, is not to come into operation immediately on the passing of the Act but with effect from an appointed day to be fixed by the Privy Council, who will doubtless first wish to be satisfied that sufficient posts are available to absorb the candidates successful at qualifying examinations."

Some anxiety, the President said, had been expressed in the House of Lords as to whether enough posts will be found before the appointed day is fixed, and as to whether they will be adequately paid. In reply Lord Shepherd had expressed the Government's opinion and intention "that these interns shall occupy house-posts, and that the rate for the job shall be paid."

The Bill, continued the President, proposed that disciplinary jurisdiction under the Medical Acts shall be transferred from the council as a whole to a committee known as the Medical Disciplinary Committee, appointed by the council.

> "The committee are to consist of the President, who will be chairman, and 18 other members, of whom at least 6 are to be elected members and at least 2 lay members of the council. Disciplinary cases are normally to be heard by not more than 9 members of the committee, and arrangements are to be made for securing that at least 1 layman is eligible to attend every hearing. Cases are only to be heard by more than 9 members if it appears to the President, or a member of the committee authorised by the committee to act on his behalf, that there are circumstances requiring the presence of a greater number. In either event, the quorum of the committee is to be 5; and since all acts of the committee are to be decided by the votes of a majority of the members present, the President is relieved after more than 90 years of the apprehension of having to give the casting vote which in business other than discipline will still be his under the Act of 1858."
>
> "Specific power is conferred upon the committee to administer oaths and to compel the attendance of witnesses and the production of documents by subpoena," and "an interesting change in long-standing practice is made by a requirement that the rules shall provide for the committee to record a finding of 'not guilty' in cases of alleged infamous conduct in a professional respect in which they judge that the allegation has not been proved."
>
> "Appeals are to lie to the Judicial Committee of the Privy Council, whose comprehensive jurisdiction and unimpeachable standing have, I think, won them unanimous acceptance both in the House of Lords and elsewhere as the best tribunal to whom the persons concerned could possibly resort."

The effect of the Bill was to increase the number of members of the council to 47. There would be 11 elected members instead of 7; there would be 8 Crown nominees instead of 5 (5 being registered medical practitioners and 3 laymen); and representation was given to the Royal College of Obstetricians and Gynæcologists. The President hoped that the Bill would go far to meet two criticisms of the present system. Of late years, and not only under the pressure of a great war, it had been felt that disciplinary business was inevitably absorbing the attention of the council as a whole to the detriment of their educational business: and that such educational business as was done was, again inevitably, concentrated in the hands of too few members, at the loss of contributions of value from the whole body. Conversely, while every member had been anxious to take his share in disciplinary business as one of his obligations, some members were less convinced than others of their aptitude for judicial work, and would be glad to be set free to concentrate their energies on the many-sided problems of medical education.

Professor Campbell concluded his address by expressing the council's appreciation of the spirit in which the Lords most concerned had addressed their minds in the amendment and improvement of the Bill.

Disciplinary Cases

POSTPONED JUDGMENTS

The council did not direct the Registrar to erase from the Register the names of the following practitioners who appeared for postponed judgment: *Hugh Boyd Gillespie*, registered as of 16, Blairhall Avenue, Langside, Glasgow, M.B. Glasg. (1935); *William Allan*, registered as of 31, Hill Crest, Burnley Road, Sowerby Bridge, Yorkshire, M.B. Glasg. (1926); *Malcolm Andrew Graham-Yooll*, registered as of Elm Tree House, Pembroke, M.B. Edin. (1923); *Norman Fraser Stock*, registered as of 4, Priestfield Road, Edinburgh, M.B. Edin. (1935); and *Francis Murray*, registered as of 417, Evelyn Street, London, S.E.8, M.R.C.S. (1930).

resented a breakdown of the service. Among other asures, he proposed that all hospitals should set aside % of their beds for the treatment of tuberculosis es. If the teaching hospitals were unable to do this. y should allocate 10% of their nursing staff for work sanatoria. Tuberculosis nurses must be fully protected preventive measures, including immunisation. and by ovisions guaranteeing them adequate financial support ould they contract the disease in the course of their ork. The value of B.C.G. vaccination had been amply monstrated in other countries. and this method of ophylaxis should be widely used here. In supporting e resolution. which was carried unanimously, Dr. A. L. COBS pointed out that many young doctors were norant of the common features of pulmonary tubercu- sis, since they rarely saw cases in the teaching hospitals.

A resolution moved by Dr. A. G. SIGNY urged that e teaching hospitals be brought under the control of e regional boards in England as they are in Scotland. he gap between the standards of teaching and non- aching hospitals. he declared. was increasing. owing the vastly different financial positions of the two oups under the N.H.S. A "levelling upwards" could ly be achieved by unified control.

Dr. A. RAPOPORT initiated a long discussion on general ractice. He urged that the greatest publicity be given o the Collings report, which should be discussed on the idest scale. The report had been much criticised, but he facts it revealed had not yet been seriously refuted. he meeting agreed that the widespread adoption of roup practice from health centres was essential for the olution of this problem. and that a satisfactory general- ractitioner service must be a full-time salaried service.

Dr. R. TEPPER drew attention to the serious difficulties acing hospital registrars. owing to their professional nsecurity. He vigorously rebutted the suggestion that he salvation of registrars lay in their mass emigration. Ir. H. SANSOM deplored the existence of a colour bar hich prevented many medical students from finding atisfactory living accommodation and from making dequate professional and social contacts in this country. Other resolutions on a crowded agenda called for the ntroduction of a forty-hour week for all health workers. and for checks on the prescribing of proprietary medicines.

A presentation was made to Dr. D. Elizabeth Bunbury and Dr. L. T. Hilliard on their retirement from office in the association. The officers for 1950–51 are: president, Mr. SOMERVILLE HASTINGS; vice-presidents, Dr. JOULES and Dr. D. STARK MURRAY; hon. secretary, Dr. GILLILAND; hon. treasurer, Mr. H. H. BARST; hon. editor of the *Bulletin*, Dr. H. I. WINNER.

Public Health

Statistics for Eire

THE following statistics for Eire in 1949 have been reported[1]:

Births.—The rate was 21·4 per 1000 population—0·5 below the rate for 1948. Illegitimate births accounted for 3·1% of the total.

Deaths.—The rate was 12·7 per 1000 population, being 0·5 above the rate for 1948. The death-rate from pulmonary tuberculosis was 0·7 per 1000, and from other forms 0·2, the rates for 1948 being 0·8 and 0·2. Deaths from puerperal causes were at the rate of 1·6 per 1000 births registered (0·1 from puerperal infection and 1·5 from other puerperal causes), compared with 1·4, 0·2, and 1·2 for 1948. The infant-mortality rate was 51 per 1000 births registered, compared with 49 in 1948.

The population at the middle of 1949 is provisionally estimated at 2,991,000.

In England Now

A Running Commentary by Peripatetic Correspondents

SATED with coloured string and raffia, poster paints, looms, and cross-stitch, occupational therapists may like to consider a new way of hand-printing which I saw demonstrated the other day. All they need is a strip of linoleum about 18 in. long and 6 in. wide, some plastic paint, one of those rubber things house-painters use for putting a fine oak grain on otherwise inoffensive doors, a chip of wood, and an old sheet or some such thing to print on. You cover the lino nice and thickly with paint, then take your grainer (or whatever it may be called) in hand, and trace any little fine pattern you like on the wet surface—delicate scrolls of fine lines, shell-like spirals, ribbons, or wreaths of mist. Then to give the design a bit of body you take your chip and add a few crosses or stars, flowers or stripes, at convenient intervals. After that you turn the strip of lino over on to the fabric and thump it down with a stone. The result is quite lovely, much finer and more delicate than a lino cut, and of course much less trouble to do. I saw this "scraper printing," as it's called, demonstrated at a show given in London by Bocquet and Freeman (who invented the method). They live at 20, Mount Pleasant, Cheshunt, Herts, and as far as I can make out the whole family spends its time hand-printing: one exceptionally nice design was done by an eight-year-old daughter. But think what outlets it gives for the troublesome or unstable: plenty of thick luscious paint to slap about, plenty of scope for creative urges, a fine opportunity to work off aggression in thumping down the lino with a large smooth stone, a rewarding result for relatively little trouble, and a chance to put any bit of old stuff to a new and pleasant purpose. I can hardly wait to begin.

* * *

Since I came to live in Blankshire I have been impressed by the number of women in the countryside and the little towns who seem to bear a vague family resemblance to one another—broad stout women with fat kindly faces and rather slow pleasant voices. They are recognisable everywhere. Even in these hilly and isolated districts where there is much intermarriage, they could not all be relations. Then it struck me that, of course, I was looking at all stages of thyroid deficiency in a mild and pleasant community, ranging from the almost normal to extreme myxœdema. This last is exemplified in the owner of a greengrocer's shop in a little seaside town forty miles from here. Customers haunt the shop to gaze at her vast bulk and listen to her good-natured croak, and I have often myself looked at her with awe, reflecting that her proper place should be Examiners' Hall.

It is perhaps only by chance that a woman in my own hamlet has an adenoma of the thyroid, said to be benign, and a boy of 12 living opposite her has a conspicuously enlarged thyroid gland. But many of the people one sees about display developmental anomalies that one would not expect to find in a rich agricultural county, though they are common enough among the poor in towns—figures too slight or too squat: features out of proportion: large faces with a suggestion of acromegaly: small faces (especially in the men) as though the bones have hardly grown since childhood: or slight exophthalmos. The children in the nearby village, I notice, are fine as babies: but after the age of 3 or 4 years they often get pale and skinny, and though lively enough they suffer far too much from respiratory affections and illnesses of every kind. Even on our hill-top, where the well-fed children (and on the whole they are well fed) should be models of health, there is frequent sickness; nearly all of the twenty-odd youngsters are small for their age—one girl of 10 who is exceptionally well grown is nevertheless sallow and languid—and all are pale except two 3-year-olds. Three children are obviously subnormal mentally.

It looks as though there may be a deficiency of iodine, and perhaps also of trace elements, throughout the county.

Then there are the tadpoles. In our garden we have a very small concrete pool which we planted last year with

LONDON EXECUTIVE COUNCIL

The First Two Years

THE largest executive council—that for the county of London—serves a population estimated at 3,389,850 in the middle of 1949. The proportion on doctors' lists under the National Health Service is still growing, the total having risen from 3,169.243 at April 1, 1949, to 3,291,270 on the same date this year.

The council's work is described by Mr. C. H. Lyon, clerk of the council, in an up-to-the-minute report on the period from July 5, 1948, to March 31 this year.

REGISTRATION

The National Health Service Act confronted the council with formidable registration difficulties which were not unlike those faced by the London Insurance Committee in the early months of 1913. In those days, partly because the index slips received by the committee were not always clearly legible, it became necessary to re-sort the index register of insured persons entitled to medical benefit into numerical (i.e., membership-number) order. In preparing for the start of the National Health Service the council was required to rearrange the index in alphabetical order. Unless the whole population could be renumbered, there was no alternative; but this rearrangement

> "once again confronted the council with the difficulties of identification and association with records already held. New registrations bearing the person's National Registration identity number cannot, with certainty, be identified with those bearing approved societies and membership numbers. A difficulty also arises with persons who change their surnames or use an alternative christian name. . . . Particularly is this noticeable in applications for ophthalmic benefit (form O.S.C.2) as the form makes no provision for statement of a maiden name. Thus the work of registration is retarded and a measure of inflation is unavoidable. Only the return to a numerical system of filing and a central index register [maintained under National Health Insurance] will, it is suggested, provide an efficient and economically maintained register, and what is even more important, reduce the coefficient of inflation."

MEDICAL PRACTITIONERS

At the inception of the service, 1918 doctors were included in the London medical list; of these 1818 were engaged in general practice. By March 31 this year the number had grown to 1958. On April 1, 1949, 219 practitioners had been given permission to employ an assistant, and by March 31 this year the total had increased to 263. The number of partnerships in the area is 238, affecting 517 practitioners (202 are in partnerships of two practitioners, 31 of three practitioners, and 5 of four practitioners). The average number of persons per list was 1656 on April 1, 1949, and 1670 on the same date this year.

The following is an analysis of the size of practitioners' lists (discounting assistants):

No. of patients	*No. of practitioners*
Nil	65
1–500	370
501–1000	185
1001–1500	183
1501–2000	176
2001–2500	187
2501–3000	177
3001–3500	185
3501–4000	151
4001–4500	94
4501–5000	65
5001–5500	49
5501–6000	31
6001–6500	22
6501–7000	10
7001–7500	7
7501–8000	1

"Practitioners," says the report, "have coöperated with the council in complying with the terms of the allocation scheme." The position on April 1, 1949, and on the same date this year was as follows:

	1949	*1950*
(*a*) Practitioners with a partner or an assistant, and a list in excess of 4000	96	157
(*b*) Practitioners without partner or assistant, and a list in excess of 4000	70	33*
(*c*) Practitioners with an assistant, but list in excess of 6400	10	7*
(*d*) Two-practitioner partnership with combined lists in excess of 8000	9	7*
(*e*) Partnerships of more than two practitioners, with total lists exceeding an average of 4000 for each practitioner	3	2
(*f*) Total no. of lists with over 1000 patients	188	206

* Application of the 5% tolerance lately authorised by the Minister of Health further reduces the numbers at (*b*), (*c*), and (*d*) from 33, 7, and 7 to 7, 3, and 4.

The average number of patients per principal differs widely between the various boroughs, ranging, at Dec. 31 last year, from 3266 in Greenwich to 525 in Hampstead.

Grants for training assistants have been approved in 48 cases, and at March 31 this year 30 practitioners were training assistants. Practitioners receiving fixed annual payments at March 31, 1949, totalled 150.

During the period ended March 31, 1949, the Medical Practices Committee declared 6 vacancies. In 48 cases practices were dispersed. In addition, 27 practitioners withdrew who had not accepted any patients, while in 31 cases practices were transferred to a practitioner regarded as the "logical successor."

In the period from April 1, 1949, to March 31, 1950, the 103 withdrawals were dealt with as follows: vacancies advertised, 14; practices dispersed, 48; practitioners with no patients, 10; practices transferred to "logical successor," 31.

OTHER FEATURES

Applications for glasses.—The number of applications seems to be decreasing slightly. For each month in 1949 and the first quarter of this year the average daily figures were as follows: *2302, 2477, 2508, 2115,* 2056 1827, 1570, 1513, 1786, 2057, 1758, 1303, 1518, 1733, and 1836.

Dentists.—The number of dentists available grew from 435 at July 5, 1948, to 1069 at March 31, 1949, and 1090 at March 31 this year.

Pharmaceutical Service.—The monthly total of prescriptions increased from 887,036 in July, 1948, to 1,234,993 in August, 1949; and the average cost per prescription from 26·63*d*. to 38·45*d*.

Foreign Visitors.—In the year ended June 30, 1949, 1093 visitors to this country received medical treatment while temporarily resident in London; and during the period from July 1, 1949, to March 31, 1950, a further 2879 were treated.

Estimates.—Gross expenditure in the current financial year is estimated at £11,352,825, of which £102,825 will be required for administration; £2,750,000 for general medical services, £2,500,000 for pharmaceutical services, £3,500,000 for general dental services, and £2,500,000 for supplementary ophthalmic services.

SOCIALIST MEDICAL ASSOCIATION

THE twentieth annual general meeting of this association, held in London on May 20 and 21, was attended by health workers from all parts of Great Britain. Mr. SOMERVILLE HASTINGS, M.P., presided.

Dr. I. C. GILLILAND moved a comprehensive policy resolution on behalf of the council. This called for the provision of health centres, and for the introduction of an industrial health service integrated with the present health services. It opposed the imposition of any charges for benefits under the N.H.S., and urged that all grades of health workers be employed on a full-time salaried basis.

An emergency resolution on the tuberculosis service was moved by Dr. HORACE JOULES, who declared that the time-lag of many months between the diagnosis of pulmonary tuberculosis and the initiation of treatment d were compensated with digitalis before operation, ile another minor group showed renal insufficiency fore operation. All of them died, mostly within a year ter operation.

In the patients with primary malignant hypertension the control series the time of observation was counted om the date of their first symptoms even if the retinal udates were first observed later. In the operated ries the time of observation was always counted from e operation. This method of calculation gave a higher gnificance to the difference between the operated and on-operated patients than is shown by the figures.

The period of observation has been divided into one-ar intervals. The mortality-rate is expressed in rms of deaths per 1000 patients per annum.

The table shows that the prognosis is constantly better the operative than in the control series. In patients ith retinal exudates the difference is highly significant both sexes and also in men belonging to group III. he significance of the lower mortality-rate in operated omen in group III is less than in men, but still 60%. n the more favourable group II we need a longer follow-p time to decide if the neurosurgical treatment signifiantly improves the prognosis, but we already have early twice as high a mortality-rate in the male controls s in the operated series in this group and no mortality mong 58 operated women against 21 deaths in 122 ontrols.

Our figures demonstrate the importance of reckoning he prognosis in hypertensive men and women separately; he life expectancy in patients without retinal exudates is wice as high in men as in women.

Sundsvall, Sweden. SVEN HAMMARSTRÖM.

SIR,—I have read with great interest the article of April 8 by Professor Platt and Dr. Stanbury. Sympahectomy in arterial hypertension has been extensively studied in Italy since 1924 when my teacher, Prof. Nicola Pende, demonstrated its physiopathological basis and ndications at the Congress of Internal Medicine at Padua.

The physiological principles in sympathectomy were being worked out as early as 1904, when Professor Pende was performing experimentally adrenal denervation with resection of the splanchnic and solar plexuses. This resulted in slow atrophy of the adrenal medulla and—an interesting fact—operation on the left side led, in his experiments, to adrenal medullary atrophy on the right side also. From clinical observations on essential hypertension, the modern researches of Goldblatt, and the undeniable importance of the kidney and adrenal gland in the genesis of hypertension, one can conclude that the splanchnic plexus and abdominal angiospasm play an important part in essential hypertension.

This concept is universally accepted today; disagreement arises only over the selection of cases for sympathectomy, and the modifications of the operation originally devised by Pende, which consists essentially in the resection of large and small splanchnic nerves on the left side. The only indication for operation is pure essential hypertension. It is necessary to exclude cases with a blood-urea over 50 mg. per 100 ml., with hyposthenuria, with sclerosis of the aorta or coronary vessels, with a diastolic blood-pressure exceeding 130–140 mm. Hg, or with serious changes in the fundus oculi. But one can obtain dramatic results even in patients who have had a cerebral catastrophe or who have incipient sclerosis of the retinal vessels, and also in subjects over 50 years of age.

The statistics of Italian surgeons such as Donati, Alessandri, Pieri, Arrigoni and Ciminata, Giordano, Valdoni, Ciceri, Stropeni, Mingazzini, and Bani, show that Pende's operation gives very favourable results; and all admit that even if the blood-pressure is not greatly lowered symptoms are relieved and working capacity improved. We have no sure evidence on the natural evolution of permanent hypertension, and we cannot therefore declare that only mild hypertension has been benefited by sympathectomy. On the other hand, we know that the condition of patients long regarded as having mild benign hypertension can suddenly deteriorate, with serious disturbances of the general circulation; cerebral hæmorrhage; left-sided cardiac failure with attacks of cardiac asthma, pulmonary œdema, or angina pectoris; or nephrosclerosis and uræmia.

The operative mortality with Pende's operation, limited to left subdiaphragmatic splanchnicotomy, is nil. We believe that the operation suggested by Pende, and the modifications and the extensions of this operation, can, in a large proportion of well-selected cases, give either real recovery or greater improvement than any medical treatment. This opinion is shared by the French surgeons, Fontaine and Leriche; by American surgeons; and also by J. Quénu and M. Gandy, who in their book on surgical technique have declared Pende's procedure to be the operation of choice.

BLOOD DESTRUCTION IN HÆMOLYTIC DISEASE OF THE NEWBORN

SIR,—The letter from Dr. Küster and Dr. Krings in your issue of May 20 raises once more the problem of the ætiology of nuclear staining in erythroblastosis fœtalis.

Leaving aside the question of the applicability of conclusions from animal experiments such as they describe to the naturally occurring disease in man, it may be accepted as a working hypothesis that the two main factors involved are vascular damage and hyperbilirubinæmia. The nature and cause of the vascular damage remain obscure; and no claims have been made, as far as I am aware, that any present form of treatment influences it. As for the hyperbilirubinæmia, Küster and Krings seem to assume that this is a direct effect of excessive blood destruction. This appears to me to be an unwarranted assumption. Leonard,[1] reviewing 55 cases of erythroblastosis fœtalis, pointed out that there was no relation between the degree of blood destruction, as estimated by the extent of the anæmia, and the severity of the jaundice. The two factors varied independently of each other. She attributed the jaundice in great part to impaired liver function.

Two conditions may be cited in which these factors can be observed in isolation. Acholuric jaundice, when it appears in newborn infants, is characterised by acute anæmia due to episodic destruction of the abnormal erythrocytes. In most cases this anæmia is not associated with jaundice. Abt [2] is categorical on this point: "When the illness is first manifested in early infancy jaundice may be entirely absent, even though there is indisputable evidence of a considerable increase in destruction of blood." This is supported by David and Minot,[3] who state: "In the infant icterus is usually slight—pallor and splenomegaly being the most outstanding physical findings." Thus anæmia of severe degree due to in-vivo blood destruction can occur with little or no appreciable jaundice.

In the so-called physiological jaundice of the newborn it has been demonstrated by Findlay et al.[4] that the icterus is not due to excessive blood destruction but almost certainly to hepatic inefficiency. In these cases there is certainly a fall in blood values during the period

4. Findlay, L., Higgins, G., Stanier, M. W. *Arch. Dis. Childh.* 1947, 22, 65.

a pygmy water-lily, some watercress, and, at the edges, arum lilies. This early spring Nature provided filamentous algæ, dragonfly nymphs, two newts, and numerous *Culex* larvæ, so I added two goldfish to eat the larvæ. Only frog spawn was missing. Children, however, have a natural affinity for these things, and very soon two jam-jars arrived in small hands, providing enough tadpoles to make the pool a home from home for the goldfish. All went well. The fish throve, the mosquitoes disappeared, the dragonflies emerged and flew about the garden; by mid-May the water-lily and the arums blossomed (yes, this *is* England). The tadpoles wriggled their tails and ate. Then we decided to buy a hose to replace ours lost in the war, and naturally went on to fill the pool to capacity. It took a lot of water, for the pond, though shallow, slopes gently at each end and has more surface than we thought; but it looked nice when full. Now, I am beginning to grow uneasy. The tadpoles have doubled their bulk since the pond was filled but show no signs of metamorphosis; before that a few had developed rudiments of hind legs, but these have now vanished—swallowed up in fat, perhaps! It would take a modernistic schizophrenic writer to describe the sinister little pool crowded with enormous infantile tadpoles, always eating. Through the clear water one sees the floor dotted with the bloated creatures resting between meals. The algæ have nearly disappeared; but disturb what is left and swarms of stout tadpoles that have been feeding on it will emerge. The watercress quivers all day with jostling bodies, and the water between the green leaves is black with a heaving mass. They fling themselves avidly on any drowned slug or worm, which quickly disappears. As I watched them I was reminded of the large myxœdematous women crowding buses, streets, village stores, and shops always seeking food (true, not for themselves but for their families). The goldfish remain invisible and perhaps feel much as would delicately nurtured white women of high rank on the films when abandoned in a kraal of Hottentots.

The common factor in the environment of humans and tadpoles seems to be our drinking-water. I cannot help asking myself whether, in the case of the tadpoles, a large influx of this water has changed the rhythm of metamorphosis because there is something anti-thyroid about it. Anyway, it is adult frogs I am aiming at and not ranine Peter Pans; so next time I go into the town I am going to get some thyroid extract for them.

* * *

The greatest tragedy in medicine is a beautiful theory slain by an ugly fact. Throughout the weekend, my H.P. had been struggling with an asthmatic who had stubbornly resisted all the usual remedies for bronchospasm. On Monday morning he invited my coöperation with a new machine devised to administer some adrenaline preparation by inhalation. Having been duly assembled the thing proceeded to do its stuff with a reassuring purr, and within 10 minutes the patient's dyspnœa was completely relieved.

Alas! with an inquisitiveness bred by admiration out of ignorance I then inspected the apparatus and discovered that owing to faulty valves it had not been working at all. And if this was not a bad enough start for the week, I was next introduced to a striking developmental anomaly, one of incomplete fusion of most of the upper part of the body. "There's a familial incidence," exclaimed the H.P. excitedly; "his sister has a hare-lip. We *must* send all the details to Dr. Parkes Weber." "She's the patient's wife, not his sister," quietly observed an iconoclastic staff nurse.

* * *

After old Joe Honeysuckle had been away a long time his daughter reported that he would not be coming back to tend the garden, because he had "persistent amenia," a diagnosis which got me guessing until I heard that he was being treated with liver injections.

Letters to the Editor

SYMPATHECTOMY FOR HYPERTENSION

SIR,—In your leading article of April 22, you refer to the need for more knowledge of the prognosis in hypertensive cases not treated surgically, for the purpose of comparison with operative series. Such a comparison has been made by Keith, Woolf, and Gilchrist[1] and recently by Bechgaard and myself.[2]

We compared the prognosis in a consecutive series of 251 cases submitted to lower dorsal or lumbodorsal sympathectomy at Olivecrona's clinic at the Serafimer Hospital, Stockholm, with a non-operative series of 453 cases followed up for 2–10 years. The control series was selected by the same principles as the surgically treated cases from about 130,000 records from hospitals in Copenhagen and Stockholm. We divided our patients into four groups and used a new classification of hypertensive disease, based on the signs and symptoms, which we have found essential in judging the prognosis. Men and women are dealt with separately.

Group I is not included in our study, for it contains cases with uncomplicated hypertensive disease without marked subjective symptoms. We do not believe that sympathectomy is justified in this group, where we know life expectancy to differ little from that of normotensives.

Group II includes those with marked subjective symptoms but without signs of myocardial damage. They may show left axis deviation in the electrocardiograph (E.C.G.) and/or relative enlargement of the left ventricle if the heart-volume is within normal limits according to teleradiography. The retinal changes in the patients in our second group are classified as group I or II according to Keith and Wagener.

Group III includes those with the same eyeground changes or, in addition, retinal hæmorrhages with or without signs of thrombosis of the retinal vessels. Patients in group III further show one or more of the following signs of cardiovascular damage: negative T_1 in the E.C.G., heart-volume above the predicted normal (500 c.cm. per sq. m. body-surface in men and 450 ml. per sq. m. in women, or the transverse diameter of the heart greater than one-half the inner thoracic diameter), residual damage after cerebral insult, and constant albuminuria.

COMPARISON OF PROGNOSIS IN 453 UNOPERATED HYPERTENSIVES AND 251 HYPERTENSIVES AFTER SYMPATHECTOMY

—	IV		III		II	
	Men	Women	Men	Women	Men	Women
Unoperated:						
No. of cases	69	25	83	94	42	122
Deaths	68	24	57	44	9	21
Mortality-rate (per 1000)	307	330	181	80	41	20
Operated:						
No. of cases ..	38	41	35	50	29	58
Deaths	18	16	9	8	4	0
Mortality-rate (per 1000)	150	96	52	33	25	..
Error of mean of differences (per 1000)..	80	115	56	37	42	45
Significance of differences of means in unoperated and operated patients (%)	93·5	98	98	59·3	30	..

In *Group IV* we include all hypertensives with definite retinal exudates and/or papillary protrusion, since we found the life expectancy to be about the same if the patients in this group did or did not have papillary protrusion.

Patients with cardiac decompensation at rest, auricular fibrillation, myocardial infarct, or renal insufficiency were not included in the non-operated series. A few patients in the operated series had cardiac insufficiency

1. Keith, M. A., Woolf, B., Gilchrist, A. R. *Brit. Heart J.* 1949, 9, 287.
2. Hammarström, S., Bechgaard, P. *Amer. J. Med.* 1950, 8, 53.

were compensated with digitalis before operation, ile another minor group showed renal insufficiency fore operation. All of them died, mostly within a year er operation.

In the patients with primary malignant hypertension the control series the time of observation was counted om the date of their first symptoms even if the retinal udates were first observed later. In the operated ries the time of observation was always counted from e operation. This method of calculation gave a higher gnificance to the difference between the operated and on-operated patients than is shown by the figures.

The period of observation has been divided into one-ear intervals. The mortality-rate is expressed in erms of deaths per 1000 patients per annum.

The table shows that the prognosis is constantly better n the operative than in the control series. In patients vith retinal exudates the difference is highly significant n both sexes and also in men belonging to group III. The significance of the lower mortality-rate in operated women in group III is less than in men, but still 60%. In the more favourable group II we need a longer follow-up time to decide if the neurosurgical treatment significantly improves the prognosis, but we already have nearly twice as high a mortality-rate in the male controls as in the operated series in this group and no mortality among 58 operated women against 21 deaths in 122 controls.

Our figures demonstrate the importance of reckoning the prognosis in hypertensive men and women separately; the life expectancy in patients without retinal exudates is twice as high in men as in women.

4. Findlay, L., Higgins, G., Stanier, M. W. *Arch. Dis. Childh.* 1947, 22, 65.

of the jaundice, but this fall continues for a considerable period after the jaundice has disappeared.[5] The two conditions are for a time coincidental but there is no direct causal relation between them.

The same state of affairs appears to me to exist in erythroblastosis fœtalis. There are three processes at work: (1) the anæmia due to the destruction of the sensitised erythrocytes; (2) vascular damage of uncertain type and unknown cause; and (3) hepatic dysfunction, also of doubtful origin.

The claim that replacement transfusion will reduce the incidence of kernicterus seems thus to be based on faulty reasoning. It may do so, but the matter certainly requires proof; and I suggest that a controlled experiment such as that suggested by Mollison and Cutbush[6] is very definitely needed. Replacement transfusion is not entirely devoid of risk. I know of two cases in which sudden death, apparently due to acute heart-failure, occurred while the replacement was being effected. The risk, whatever its magnitude, may well be worth taking if it can be shown that the procedure does reduce the incidence of kernicterus. However, I feel that at the moment there are too many enthusiasts and not enough critical observers at work in this field.

Derbyshire Hospital for Sick Children, Derby. DUNCAN MACAULAY.

AUREOMYCIN AND SULPHADIAZINE IN ABORTUS FEVER

SIR,—In the following case of abortus fever 'Aureomycin' and sulphadiazine were administered together:

The patient was a farmer, aged 45, who, with a sore on his thumb and abrasions on both hands, had attempted to deliver a cow of a stillborn calf. Unable to do so, he called in a veterinary surgeon, who diagnosed ruptured uterus; the calf was dead. Two weeks later the farmer began to feel out of sorts; he was easily fatigued and irritable, and had occasional headaches; and on Jan. 8, having become feverish, he had to take to his bed. His own doctor first saw him on Jan. 11, when the chief symptoms were headache, aching limbs, heavy sweats, and constipation. Examination did not reveal any signs other than fever (100°F); pulse-rate 90 per min. During the next few days, no additional signs developed, and the cause of the fever was not suspected, since no history had been elicited regarding this man's obstetric performance (which had included an intra-uterine examination).

A Widal agglutination test on Jan. 15 was completely negative. A white blood-cell count showed leucopenia with pronounced increase in mononuclear cells (white cells 6500 per c.mm.; polymorphs 45%, lymphocytes 20%, monocytes 35%).

Since the clinical condition did not improve, and the pyrexia, tachycardia, sweats, and headache continued, a second Widal test was made on Jan. 19; and a standard suspension of *Brucella abortus* was agglutinated at a titre of 1/1280.

On admission to hospital on the 16th day of the known febrile state (Jan. 22) and six weeks after the infection was contracted, this patient's general condition was good, considering the duration of the fever. Pulse-rate 120 per min.; temperature 100°F. He was somewhat disorientated and could give no clear account of his illness. The abdomen showed moderate generalised distension; the spleen was not palpable. Headache, of varying intensity, was referred to the frontal region, and was usually most severe in the early evening. After a drenching sweat in the late evening of each day, the headache became less intense and the fever abated, rising again gradually to 100°F about 6 P.M. An enema on the morning after admission relieved the abdominal distension and produced a formed fæcal mass which had a heavy putrid odour resembling hydrogen sulphide gas.

Bacteriological examination of this stool and of three consecutive specimens of urine revealed no *Br. abortus*; blood-culture was also negative. A rising agglutination titre was found in consecutive specimens of blood-serum and on Feb. 13 the titre was positive at 1/5120.

The newer antibiotics have been used in the treatment of abortus fever, and streptomycin combined with sulphadiazine produced a cure in a severe case.[1] Aureom therapy is reported to have proved successful in three cases. I decided to use aureomycin because it could be given in capsules by mouth.

Oral therapy with aureomycin hydrochloride in a dosage of 500 mg. six-hourly was commenced at 10 P.M. on Jan. No signs of intolerance were observed, and at the end twenty-four hours the dose was increased to 1 g. six-hourly. This dosage was continued for four days, but no signs of clinical improvement, other than a slight reduction in the pulse-rate, were apparent. Headache, fever, and sweats continued. On the evening of Jan. 29, sulphadiazine therapy —2 g. initially followed by 1 g. four-hourly—was commenced. Within thirty-six hours the patient's condition improved greatly. The temperature fell to normal; the pulse-rate was reduced; headache was less intense; and the stool obtained after an enema was not offensive in odour. Within seventy-two hours the pulse-rate decreased further, headache and sweating ceased, and an uneventful convalescence was established.

On the third day of normal temperature the dosage of aureomycin and sulphadiazine was reduced by half, and was continued at this level until one week of freedom from headache, sweats, and fever had elapsed. The patient was discharged from hospital on Feb. 15, six weeks after the onset of the known febrile state. He has not relapsed.

During the last week of March, a record of the patient's evening temperature showed him to be afebrile; a blood culture was negative; and his blood-serum agglutinated a standard suspension of *Br. abortus* at a titre of 1/250 (highest When last heard of, on April 4, he was well and doing a full day's work.

Thus in this case aureomycin alone caused no clinical improvement; but aureomycin and sulphadiazine together were successful.

I wish to thank Dr. L. M. Dowsett, director of the Emergency Public Health Laboratory, Norwich, for the bacteriological work, which indicated the diagnosis in this case

Isolation Hospital, Dereham, Norfolk. A. J. O'CONNOR.

SOCIAL PHILOSOPHY OF WILFRED TROTTER

SIR,—Thirty years and more have passed since Wilfred Trotter closed his preface to *Instincts of the Herd in Peace and War* with the words:

> "The method I have used is frankly speculative, and I make no apology for it because the facts are open to the observation of all and available for confirmation or disproof. I have tried to point out a way; I have tried not to exhort or persuade to the use of it—these are matters outside my province."

So far as I am aware, no concerted attempt has been made to experiment with the use of the way indicated, and in default of such a follow-up it has become fashionable in some sociological circles to say that Trotter's approach to social problems is now discredited; I would say, on the contrary, that those who have gone to the facts for confirmation or disproof have found ample support for nearly all his main assertions. It is probable that only a very few of his readers have grasped the implications of his conception of a unitary organism based upon a number of human minds, considered in conjunction with the tendency of maturing minds to differentiate either towards a "resistive" or towards a "mentally unstable" type. There must however be some who believe with me that *Instincts of the Herd* deserves more serious consideration than it has yet received. If any such will be good enough to write to me, I should like to send a further communication, which will include an invitation to take part in a discussion and conference on the social philosophy of Wilfred Trotter, at Braziers Park during the weekend of July 1–2.

UMIN-ACTIVE ANTISERA IN RHESUS TYPING

R,—Dr. Stirk has raised a very important question is article of May 13. I agree that albumin-active sera can be used to advantage in hospital practice; indeed they have been used with success in this on during the past eighteen months. The methods ch Dr. Stirk advocates are, however, open to serious cism.

he specificity of his antisera is unknown. About ird of them are likely to contain rhesus antibodies er than anti-D, and possibly other antibodies outside Rh system. The antisera are not absorbed, and erience has shown that the use of such antisera is ught with danger. The additional reagents from which election must be made increase the chances of error. ne is wasted in emergency transfusions since the BO group of the recipient must first be determined fore the correct anti-D serum can be selected, instead grouping and Rh typing at the same time; and the ndency will be for one or other or both tests to be urried. An error in grouping (false negative) which ay be harmless—e.g., a B, Rh-negative recipient rongly grouped as O—may be converted into a serious ror (false positive) if, as Dr. Stirk recommends, anti-D rum obtained from an A or O mother is employed.

Dr. Stirk states that Rh antisera obtained from nmunised AB mothers can be used against all unknown ells. This, of course, is not precisely true, for quite part from the fact that the specificity of his antisera s unknown, some 25% of A_2B individuals possess anti-A_1 in their serum. And how often would he find a suitable anti-Rh serum from an AB mother? He collected altogether seven suitable antisera in a year: at that rate the probabilities are that only one from an AB mother would be found in the course of four years.

There is nothing in his paper to suggest that Dr. Stirk uses known Rh-positive and Rh-negative cells as controls. It would appear, therefore, that, with the technique recommended there are no direct means of showing whether false positives and/or false negatives do or do not occur. The technique is, however, claimed to be reliable on the following grounds: (*a*) 14% of 206 patients were found to be Rh-negative while the average for the English population is 14·94%; (*b*) false positive reactions are greatly minimised, if not entirely removed, by using two different sera for each test. A little reflection will show that neither of these statements provides evidence of the reliability of the method. Furthermore, the comparison between his figure of 14% and the average figure of 14·94% is a false one because the latter figure refers to true Rh-negatives only (cde/cde) whilst the former refers to cde/cde persons plus an unknown number of Rh-positives—viz., D-negatives possessing the antigens C or E.

The use of albumin-agglutinating anti-D sera should be encouraged, but not their haphazard and uncontrolled use. In this region saline and albumin-agglutinating anti-D sera are issued to hospitals under certain conditions:

1. At least one member of the staff of the pathology department or at least one resident medical officer must have undergone one week's course of training in blood-grouping, Rh typing, and cross-matching at the regional transfusion centre; or, alternatively, must have been adequately trained in this work by the area pathologist.

2. The hospital blood-bank and all testing sera should be controlled by one person—usually the pathologist, a responsible member of his staff, or a responsible resident medical officer.

3. Samples of blood, from more or less permanent members of the hospital staff, must be sent to the regional transfusion centre for grouping and Rh genotyping, so that selected Rh positive and negative control cells will always be available when patients are to be grouped and Rh typed.

4. When these conditions have been fulfilled (or are said to have been fulfilled) selected absorbed specific anti-D sera are issued, their specificity having previously been checked by the Blood Group Reference Laboratory, Lister Institute. The sera are of two varieties, selected for their suitability for use with two techniques: (*a*) saline anti-D for use with the standard tube technique, for planned transfusions; and (*b*) albumin anti-D for use with the Diamond technique, for emergency transfusions. They are not guaranteed to be suitable for other techniques.

5. For a short period after the sera are issued, the pathologist or other responsible medical officer is requested to send to the regional transfusion centre duplicate samples of blood tested in his laboratory for confirmation of results, in order that the technician or medical officer carrying out the tests may gain confidence in himself and in the techniques employed.

6. Cross-matching difficulties and anomalous results should be referred to the regional transfusion centre.

The conditions laid down are not always fulfilled, and there are many difficulties in carrying out the scheme though these are gradually being overcome.

It is hoped that this letter will help pathologists who wish to initiate or extend rhesus investigations in their hospitals to appreciate that some thought and care in planning will be required, and that a certain amount of training or special experience in this type of work would not be a disadvantage.

R. H. MALONE.

T.E.A.B. IN RHEUMATOID ARTHRITIS

SIR,—As an outcome of Dr. Howell's report of Feb. 4, and the subsequent letter from Dr. Heyman and his colleagues in your issue of April 1, I should like to state briefly my experiences with tetraethylammonium bromide (T.E.A.B.) in 35 cases of rheumatoid arthritis treated in the medical department of this institute.

Our reason for trying T.E.A.B. was the well-known fact that even in the more severe cases sympathectomy [1] and blockade of the sympathetic ganglia [2] have given a certain amount of relief. We, at this institute, are at present performing a systematic investigation into the reaction of the autonomic nervous system in patients with rheumatoid arthritis; and the experiences with T.E.A.B. have formed a link in these investigations of which a fuller account will be published shortly.

As a test for the function of the autonomic nervous system we use the reaction of the arteriovenous anastomoses to indirect heating. This method, described by Christiansen, Fog, and Vanggård [3] is a modification of the methods of Gibbon and Landis [4] and Uprus, Gaylor, and Carmichael.[5] By this method we found, in cases of rheumatoid arthritis, such deviations from normal in the autonomic reactions that we were prompted to see what effect T.E.A.B. would have.

We used as controls 15 medical students who were not suffering from vascular disease or rheumatoid arthritis.

After cooling the hands until the skin-temperature (measured at the pulp of the 3rd finger by thermo-elements of copper-constantan) was about 16°C, 5 ml. of 10% T.E.A.B. ('Etylon') was given intravenously during $^1/_2$ min. After 2–3 min. the skin-temperature of the finger had risen on average by 13·2°C (max. 17°C, min. 8°C). At the same time all subjects had paræsthesiæ, shivering, ptosis, paresis of accommodation, and fall of blood-pressure (by about 20%). Normal physiological conditions were re-established in 30 min.

of the jaundice, but this fall continues for a considerable period after the jaundice has disappeared.[5] The two conditions are for a time coincidental but there is no direct causal relation between them.

The same state of affairs appears to me to exist in erythroblastosis fœtalis. There are three processes at work: (1) the anæmia due to the destruction of the sensitised erythrocytes; (2) vascular damage of uncertain type and unknown cause; and (3) hepatic dysfunction, also of doubtful origin.

The claim that replacement transfusion will reduce the incidence of kernicterus seems thus to be based on faulty reasoning. It may do so, but the matter certainly requires proof; and I suggest that a controlled experiment such as that suggested by Mollison and Cutbush[6] is very definitely needed. Replacement transfusion is not entirely devoid of risk. I know of two cases in which sudden death, apparently due to acute heart-failure, occurred while the replacement was being effected. The risk, whatever its magnitude, may well be worth taking if it can be shown that the procedure does reduce the incidence of kernicterus. However, I feel that at the moment there are too many enthusiasts and not enough critical observers at work in this field.

Derbyshire Hospital for Sick Children, Derby. DUNCAN MACAULAY.

AUREOMYCIN AND SULPHADIAZINE IN ABORTUS FEVER

SIR,—In the following case of abortus fever 'Aureomycin' and sulphadiazine were administered together:

The patient was a farmer, aged 45, who, with a sore on his thumb and abrasions on both hands, had attempted to deliver a cow of a stillborn calf. Unable to do so, he called in a veterinary surgeon, who diagnosed ruptured uterus; the calf was dead. Two weeks later the farmer began to feel out of sorts; he was easily fatigued and irritable, and had occasional headaches; and on Jan. 8, having become feverish, he had to take to his bed. His own doctor first saw him on Jan. 11, when the chief symptoms were headache, aching limbs, heavy sweats, and constipation. Examination did not reveal any signs other than fever (100°F); pulse-rate 90 per min. During the next few days, no additional signs developed, and the cause of the fever was not suspected, since no history had been elicited regarding this man's obstetric performance (which had included an intra-uterine examination).

A Widal agglutination test on Jan. 15 was completely negative. A white blood-cell count showed leucopenia with pronounced increase in mononuclear cells (white cells 6500 per c.mm.; polymorphs 45%, lymphocytes 20%, monocytes 35%).

Since the clinical condition did not improve, and the pyrexia, tachycardia, sweats, and headache continued, a second Widal test was made on Jan. 19; and a standard suspension of *Brucella abortus* was agglutinated at a titre of 1/1280.

On admission to hospital on the 16th day of the known febrile state (Jan. 22) and six weeks after the infection was contracted, this patient's general condition was good, considering the duration of the fever. Pulse-rate 120 per min.; temperature 100°F. He was somewhat disorientated and could give no clear account of his illness. The abdomen showed moderate generalised distension; the spleen was not palpable. Headache, of varying intensity, was referred to the frontal region, and was usually most severe in the early evening. After a drenching sweat in the late evening of each day, the headache became less intense and the fever abated, rising again gradually to 100°F about 6 P.M. An enema on the morning after admission relieved the abdominal distension and produced a formed fæcal mass which had a heavy putrid odour resembling hydrogen sulphide gas.

Bacteriological examination of this stool and of three consecutive specimens of urine revealed no *Br. abortus*; blood-culture was also negative. A rising agglutination titre was found in consecutive specimens of blood-serum and on Feb. 13 the titre was positive at 1/5120.

The newer antibiotics have been used in the treatment of abortus fever, and streptomycin combined with sulphadiazine produced a cure in a severe case.[1] Aure therapy is reported to have proved successful in three I decided to use aureomycin because it could be giv capsules by mouth.

Oral therapy with aureomycin hydrochloride in a d of 500 mg. six-hourly was commenced at 10 P.M. on Jan. No signs of intolerance were observed, and at the end twenty-four hours the dose was increased to 1 g. six- This dosage was continued for four days, but no sign clinical improvement, other than a slight reduction in pulse-rate, were apparent. Headache, fever, and continued. On the evening of Jan. 29, sulphadiazine t —2 g. initially followed by 1 g. four-hourly—was comme Within thirty-six hours the patient's condition imp greatly. The temperature fell to normal; the pulse was reduced; headache was less intense; and the sto obtained after an enema was not offensive in odour. Wi seventy-two hours the pulse-rate decreased further, headache and sweating ceased, and an uneventful convalescence was established.

On the third day of normal temperature the dosage of aureomycin and sulphadiazine was reduced by half, and was continued at this level until one week of freedom from headache, sweats, and fever had elapsed. The patient was discharged from hospital on Feb. 15, six weeks after the onset of the known febrile state. He has not relapsed.

During the last week of March, a record of the patient's evening temperature showed him to be afebrile; a blood culture was negative; and his blood-serum agglutinated a standard suspension of *Br. abortus* at a titre of 1/250 (highest) When last heard of, on April 4, he was well and doing a fu day's work.

Thus in this case aureomycin alone caused no clinical improvement; but aureomycin and sulphadiazine together were successful.

I wish to thank Dr. L. M. Dowsett, director of the Emergency Public Health Laboratory, Norwich, for the bacteriological work, which indicated the diagnosis in this case.

T.E.A.B. IN RHEUMATOID ARTHRITIS

SIR,—As an outcome of Dr. Howell's report of Feb. 4, and the subsequent letter from Dr. Heyman and his colleagues in your issue of April 1, I should like to state briefly my experiences with tetraethylammonium bromide (T.E.A.B.) in 35 cases of rheumatoid arthritis treated in the medical department of this institute.

Our reason for trying T.E.A.B. was the well-known fact that even in the more severe cases sympathectomy[1] and blockade of the sympathetic ganglia[2] have given a certain amount of relief. We, at this institute, are at present performing a systematic investigation into the reaction of the autonomic nervous system in patients with rheumatoid arthritis ; and the experiences with T.E.A.B. have formed a link in these investigations of which a fuller account will be published shortly.

As a test for the function of the autonomic nervous system we use the reaction of the arteriovenous anastomoses to indirect heating. This method, described by Christiansen, Fog, and Vanggård[3] is a modification of the methods of Gibbon and Landis[4] and Uprus, Gaylor, and Carmichael.[5] By this method we found, in cases of rheumatoid arthritis, such deviations from normal in the autonomic reactions that we were prompted to see what effect T.E.A.B. would have.

We used as controls 15 medical students who were not suffering from vascular disease or rheumatoid arthritis.

After cooling the hands until the skin-temperature (measured at the pulp of the 3rd finger by thermo-elements of copper-constantan) was about 16°C, 5 ml. of 10% T.E.A.B. ('Etylon') was given intravenously during $^1/_2$ min. After 2–3 min. the skin-temperature of the finger had risen on average by 13·2°C (max. 17°C, min. 8°C). At the same time all subjects had paræsthesiæ, shivering, ptosis, paresis of accommodation, and fall of blood-pressure (by about 20%). Normal physiological conditions were re-established in 30 min.

1. Rowntree, G. L., Adson, A. W. *J. Amer. med. Ass.* 1929, 216, 141. Bauer, E. *Nord. Med.* 1939, 2, 1048. Telford, E. D. *Lancet*, 1938, i, 70. Trauner, I. C. Über Vegetative-störungen beim Rheumatismus. Dresden, 1940.
2. Hecht-Johansen, A. *Ugeskr. Laeg.* 1944, 14; 327.
3. Christiansen, S., Fog, M., Vanggård, T. *Acta psychiat., Kbh.* 1939, 14, 413.
4. Gibbon, J. H. jun., Landis, E. M. J. *J. clin. Invest.* 1932, 11, 1019.
5. Uprus, V., Gaylor, J., Carmichael, E. A. *Clin. Sci.* 1936, 2, 301.

In patients with rheumatoid arthritis T.E.A.B. gave very different results.

Of 35 patients, 4 had no rise of skin-temperature at all; 12 had a rise of 1–3°C; 2 a rise of more than 15°C; and the remainder a rise of 5–15°C. The average rise was 6·5°C in these patients, compared with 13·2°C in the control group.

10 patients were treated for three weeks with T.E.A.B. in doses of 5 ml. intramuscularly in the morning and at noon on every other day. The dosage was arranged in this way because we found that patients often collapsed up to 6 hours after intramuscular injection of T.E.A.B.; so we had to keep them in bed for 6 hours or more after the injection. This, of course, was undesirable because of the rheumatoid arthritis, so we gave two injections on one day with a subsequent free day. During this period the only other treatment was a little massage and movements.

Of the 10 patients, 7 felt no relief at all; in 3 we found objectively less swelling of fingers, elbows, and knees, and less stiffness, but the results were in no way as good as those seen after physiotherapy, electrotherapy, and especially injection of gold sodium thiosulphate.

This conclusion was reached by clinical estimation, and it must be judged in this light. However, after three weeks' treatment with T.E.A.B. all 10 patients reacted in exactly the same way to indirect heating as before the blockade. Consequently the relief described can hardly have resulted from anything but improved peripheral circulation. As long as this is maintained, it will restrict swelling of periarticular tissues and improve joint function; but improvement by this mechanism is greater and longer continued when obtained by the common physical treatment.

Finsen Institute,
Copenhagen.

ANTON FLØYSTRUP.

STREPTOMYCIN IN ACUTE MILIARY TUBERCULOSIS

SIR,—I should like to state that, so far as choroidal tubercles are concerned, our experience in Dublin confirms that reported on May 20 by Professor Illingworth and Dr. Lorber from the department of child health, University of Sheffield. In this hospital we, too, have found no choroidal tubercles among some 100 cases of uncomplicated tuberculous meningitis seen since October, 1947. In the few cases of tuberculous meningitis where choroidal tubercles have been found, miliary tuberculosis has been present as well. *Because of this, I have taught* my students during the last two years that choroidal tubercles, while common in miliary tuberculosis, are not found in tuberculous meningitis without miliary tuberculosis.

House of Recovery and Fever Hospital,
Cork Street, Dublin.

C. J. MCSWEENEY.

ULCERATIVE COLITIS

SIR,—I was very interested in the two papers by Dr. Rice-Oxley and Dr. Truelove in your issues of April 1 and 8. Having seen a great number of cases of so-called ulcerative colitis during and since the war, I should like to call attention to the need to exclude the specific infections which may cause illnesses that may be clinically indistinguishable from it—bacillary dysentery, amœbic dysentery, and tuberculous colitis. In typical cases of ulcerative colitis I have found *Entamœba histolytica* present, and have come to the conclusion that the majority are in reality amœbic dysentery with secondary infections. A few illustrative cases can show this point:

A woman, aged 57, ill for many years, and diagnosed as having ulcerative colitis. Disorder recognised in 1946 after a contact—a girl, aged 6 years—had been taken ill with typical amœbic dysentery.

A man, aged 33, ill since 1930, having spent many months in hospital each year. *E. histolytica* found in 1947.

A woman, aged 49, ill since 1937 with "ulcerative colitis." Recognised in 1946 as amœbic dysentery; developed amœbic liver abscess in the same year.

Such cases should be treated with full doses of insoluble sulpha drugs, penicillin, and emetine bismuth iodide. I wholeheartedly agree with Professor Hardy, Mr. Dickson Wright, and others that for all practical purposes the psychological aspect of ulcerative colitis can be ignored.

London, W.1.

LEO RAU.

PROPHYLACTIC NEOSTIGMINE IN ELECTRO-CONVULSIVE TREATMENT

SIR,—In impending respiratory paralysis after curare and electrically induced convulsions, intravenous neostigmine is an effective and indispensable antidote. Up to now, however, routine injections of neostigmine do not seem to have been used prophylactically. This may be partly because of the difficulty of giving intravenous injections immediately after a convulsion, when motor excitement is still present.

There are good reasons for giving a prophylactic injection of neostigmine in every case, irrespective of the degree of curarisation. Even after apparently moderate curarisation a convulsion may be followed by inhibition of respiratory movements and even by respiratory paralysis. Immediately after a convulsion it is at first impossible to differentiate between respiratory paralysis and reflex asphyxia. Since several minutes may elapse before intravenous neostigmine takes effect, delay here is a serious disadvantage.

The following method of giving neostigmine and curare before inducing a convulsion is comparatively free from risk:

> The curare having been injected into a vein in the usual way, the needle is left in position while another syringe, containing neostigmine 1 mg., is attached to it. A pneumatic bandage (such as is used in estimating blood-pressure) previously placed proximal to the site of injection is now inflated to a pressure exceeding arterial blood-pressure—e.g., 250 mm. Hg.
>
> The neostigmine is now injected into the vein, and the needle is removed without the bandage being deflated. Slight pressure on the site of injection and later the application of surgical tape prevent hæmorrhage from the vein. As soon as a major convulsion starts, the bandage is promptly deflated. The technique is quite simple and hardly increases the treatment time.

The latent period before the action of neostigmine is appreciable is $^{1}/_{2}$–$1^{1}/_{2}$ minutes from the end of the convulsion, when the restricted movements of the thorax will be seen to become completely free in the course of 10–15 seconds. The diarrhœa and nausea often associated with neostigmine therapy and occurring during the two hours immediately after the treatment may in most cases be effectively prevented with 0·5–1 mg. of atropine sulphate.

The peripheral circulation is apt to be deficient both during and after a major convulsion with, *inter alia*, a rise in venous pressure.[1,2] To investigate whether this might seriously delay the effect of the injected neostigmine I have carried out circulation tests with fluorescein; 2 ml. of 10% sodium fluorescein was added to the neostigmine. The pneumatic bandage was deflated at the onset of a major fit, and the fluorescein could be shown with Wood's glass in the conjunctivæ in every one of 30 patients before the end of the attack.

At my suggestion treatment since August, 1948, at the department of psychiatry, South Hospital, Stockholm, has been along the following lines.

---

1. Altschule, M. D., Tillotson, K. J. *Arch. Neurol. Psychiat.* 1948, 59, 469.
2. Silfverskiöld, B. P., Amark, C. *Acta med. scand.* 1943, 113, 191.

l patients treated with electroconvulsions and curare receive ine intravenous neostigmine. No patient is given more a 1 ml. of *d*-tubocurarine (Squibb) per 20 kg. of body-ght. For the first treatment all patients receive this dose 0·5 ml. With this dosage no appreciable decrease is as le noted in the force of muscular contractions during a vulsion, but in ergograph test without E.C.T. the curare ct is clearly demonstrable.[3]

)n systematic radiography we have seen only one ior vertebral fracture among 80 cases treated up to mary, 1949.

'o exclude cases of incipient myasthenia gravis ry patient is subjected to ergograph tests[3] before lergoing the treatment.

TEACHING OF PUBLIC HEALTH

SIR,—I am much obliged to Prof. A. V. Neale for his ter in your issue of May 27 (p. 1019) with which I am complete agreement. The comment I made in the ort to which he refers was :

> "It is gratifying to us to feel that the course for the liploma in public health is broad and liberal enough to ttract students for its own sake, and its impress upon heir colleagues from overseas affords us special pleasure."

is is quite consistent with our feeling of disappointment t the *absolute* number of students entering the public alth service in this country is so small. We expressed tisfaction at the relative composition of recent diploma sses and hoped that it would be repeated in the years come.

In my inaugural address in 1944 I said :

> "In my view the primary aim of a school or university department of hygiene is to make good general practitioners in health ; to send forth keen, competent men and women with a high sense of their calling and a scientific outlook."

is our aim today to make the D.P.H. course a good -round training for general practitioners of medicine, d we do indeed lay special stress, through seminars d field studies, on the epidemiologies of the home, the ctory and workplace, the school, and the hospital. wo of our four full-time medical teachers are general actitioners of long experience, and the younger members our staff hold part-time appointments in under-aduate schools.

The University of London has offered part-time aching for the D.P.H. for many years, but no applications ve been received. I myself was a part-time student, it found it very difficult to fit in the course with the lls and distractions of general practice. Our students me as a rule with fellowships or leave of absence for year, or with a personal determination to throw emselves wholly into the work. They learn a great al from one another in the course of morning coffee, nch, or tea, as well as in the library and in the uncharted me, industrial, and hospital visits which they arrange members of seminar groups. There is something in whole-time course that knits them together in friend-ip and common purpose, and I should be sorry to lose e social and educational value of such an arrangement. ll the same, we should be happy to coöperate with one r more other universities in organising part-time teaching, nd we have in fact begun to discuss possible methods f adjustment.

I cannot imagine any more fascinating job than teach-g public health at the present time : we are constantly xperimenting and making mistakes and laughing about hem and trying to do better. The main point, however, that the students are our partners.

Parliament

Medical Bill

IN the House of Lords on May 23 the Medical Bill was read the third time and passed.

QUESTION TIME

Certificates for Sickness Benefit

Mr. READER HARRIS asked the Minister of National Insurance when she issued her directive to branch offices instructing them that a claimant might establish title to sickness benefit by furnishing certificates signed by a person other than a registered medical practitioner, such as an osteopath, Christian Science healer or dentist : by what power such a directive was issued ; and how many sickness claims had been paid on the evidence of certificates issued by persons other than registered medical practitioners.—Dr. EDITH SUMMERSKILL replied : The National Insurance (Medical Certification) Regulations, 1948, require all claimants for sickness benefit to submit evidence of their incapacity. While this evidence normally includes a medical certificate, the statutory adjudicating authorities can take into consideration alternative evidence of incapacity if they think fit. I have no power to issue directions to these authorities. The information asked for in the last part of the question is not available, but the numbers are believed to be very small.

Mr. HARRIS : Is the Minister satisfied that certificates should be accepted from faith healers, herbalists, and other persons over whom control must necessarily be very vague, and is she herself, as a registered medical practitioner, satisfied with a state of affairs whereby the Willesden Institute of Natural Healing can tout for business by issuing circulars stating that certificates are available for National Insurance purposes ?—Dr. SUMMERSKILL : This method of determining incapacity has been operating for nearly 40 years, and if the hon. gentleman was a little older he would remember the sect called the Peculiar People who have a religious objection to doctors, and who have, in fact, formed their own approved society. I am quite aware of the fact that this right which people have of exercising conscientious objection, and which we believe it is right for them to have, may be abused, but I can assure the hon. gentleman that we are keeping a careful eye on the matter and that we have certain safeguards. We have sick visitors and also regional medical officers who can be called in for further medical examinations. Mr. HARRIS : Does not the Minister draw some distinction between public funds and the funds of an approved society which were not public funds before ?—Dr. SUMMERSKILL : Really, the hon. gentleman is displaying appalling ignorance. Does he not know that, before 1948, these approved societies used both public funds and private funds ?

Mr. RICHARD EWART : Is the Minister aware that her reply will give great satisfaction to thousands of people in this country who have for many years exercised this right of freedom of choice in determining what type of treatment they should take when sick, and that her devastating reply to the prejudices of the hon. Member opposite will be gratefully received ?

National Assistance

In answer to a question Dr. SUMMERSKILL stated that at the end of April, 1950, regular weekly grants of National Assistance were being paid to 1,192,000 persons.

Sanatorium Waiting-lists

In answer to a question, Mr. A. BEVAN stated that approximately 11,000 people suffering from tuberculosis were waiting for beds in sanatoriums.

Under-doctored Areas

Mr. SOMERVILLE HASTINGS asked the Minister whether it was necessary for a doctor to provide himself with a surgery as a first preliminary to submitting his name for inclusion in the medical list as a principal in an under-doctored area.—Mr. BEVAN replied : It is not necessary for a doctor to have a surgery before he applies for inclusion, but the Medical Practices Committee may make the granting of an application conditional upon his acquiring one within a specified time.

Cost of Drugs

Mr. HASTINGS asked the Minister what was the average annual cost of drugs per insured person under the National

---

[3] Silfverskiold, B. P. *Ibid*, 1949, 135, 61.

In patients with rheumatoid arthritis T.E.A.B. gave very different results.

Of 40 patients, 4 had no rise of skin-temperature at all; 15 had a rise of 1–5°C; 2 a rise of more than 15°C; and the remainder a rise of 5–15°C. The average rise was 6·5°C in these patients, compared with 12·2°C in the control group.

10 patients were treated for three weeks with T.E.A.B., in doses of 5 ml. intramuscularly in the morning and at noon on every other day. The dosage was arranged in this way because we found that patients often collapsed up to 6 hours after intramuscular injection of T.E.A.B.; so we had to keep them in bed for 6 hours or more after the injection. This, of course, was undesirable because of the rheumatoid arthritis, so we gave two injections on one day with a subsequent free day. During this period the only other treatment was a little massage and movements.

Of the 10 patients, 7 felt no relief at all; in 3 we found objectively less swelling of fingers, elbows, and knees, and less stiffness, but the results were in no way as good as those seen after physiotherapy, electrotherapy, and especially injection of gold sodium thiosulphate.

This conclusion was reached by clinical estimation, and it must be judged in this light. However, after three weeks' treatment with T.E.A.B. all 10 patients reacted in exactly the same way to indirect heating as before the blockade. Consequently the relief described can hardly have resulted from anything but improved peripheral circulation. As long as this is maintained, it will reduce swelling of periarticular tissues and improve joint function; but improvement by this mechanism is greater and longer continued when obtained by the common physical treatment.

Finsen Institute, Copenhagen. ANTON FLOYSTRUP.

STREPTOMYCIN IN ACUTE MILIARY TUBERCULOSIS

SIR,—I should like to state that, so far as choroidal tubercles are concerned, our experience in Dublin confirms that reported on May 20 by Professor Illingworth and Dr. Lorber from the department of child health, University of Sheffield. In this hospital we, too, have found no choroidal tubercles among some 100 cases of uncomplicated tuberculous meningitis seen since October, 1947. In the few cases of tuberculous meningitis where choroidal tubercles have been found, miliary tuberculosis has been present as well. Because of this, I have taught my students during the last two years that choroidal tubercles, while common in miliary tuberculosis, are not found in tuberculous meningitis without miliary tuberculosis.

PROPHYLACTIC NEOSTIGMINE IN ELECTRO-CONVULSIVE TREATMENT

SIR,—In impending respiratory paralysis after curare and electrically induced convulsions, intravenous neostigmine is an effective and indispensable antidote. Up to now, however, routine injections of neostigmine do not seem to have been used prophylactically. This may be partly because of the difficulty of giving intravenous injections immediately after a convulsion, when motor excitement is still present.

There are good reasons for giving a prophylactic injection of neostigmine in every case, irrespective of the degree of curarisation. Even after apparently moderate curarisation a convulsion may be followed by inhibition of respiratory movements and even by respiratory paralysis. Immediately after a convulsion it is at first impossible to differentiate between respiratory paralysis and reflex asphyxia. Since several minutes may elapse before intravenous neostigmine takes effect, delay here is a serious disadvantage.

The following method of giving neostigmine and curare before inducing a convulsion is comparatively free from risk:

The curare having been injected into a vein in the usual way, the needle is left in position while another syringe, containing neostigmine 1 mg., is attached to it. A pneumatic bandage (such as is used in estimating blood-pressure) previously placed proximal to the site of injection is now inflated to a pressure exceeding arterial blood-pressure—e.g., 250 mm. Hg.

The neostigmine is now injected into the vein and the needle is removed without the bandage being deflated. Slight pressure on the site of injection and later the application of surgical tape prevent hæmorrhage from the vein. As soon as a major convulsion starts, the bandage is promptly deflated. The technique is quite simple and hardly increases the treatment time.

The latent period before the action of neostigmine is appreciable is 1/2–1 1/2 minutes from the end of the convulsion, when the restricted movements of the thorax will be seen to become completely free in the course of 10–15 seconds. The diarrhœa and nausea often associated with neostigmine therapy and occurring during the two hours immediately after the treatment may in most cases be effectively prevented with 0·5–1 mg. of atropine sulphate.

The peripheral circulation is apt to be deficient both during and after a major convulsion with, inter alia, a rise in venous pressure.[1,2] To investigate whether this might seriously delay the effect of the injected neostigmine I have carried out circulation tests with fluorescein; 2 ml. of 10% sodium fluorescein was added to the neostigmine. The pneumatic bandage was deflated at the onset of a major fit, and the fluorescein could be shown with Wood's glass in the conjunctiva in every one of 30 patients before the end of the attack.

At my suggestion treatment since August, 1948, in the department of psychiatry, South Hospital, Stockholm, has been along the following lines.

PROPHYLACTIC NEOSTIGMINE IN ELECTRO-CONVULSIVE TREATMENT

SIR,—In impending respiratory paralysis after and electrically induced convulsions, intravenous stigmine is an effective and indispensable Up to now, however, routine injections of neo do not seem to have been used prophylactically. T may be partly because of the difficulty of giving venous injections immediately after a convulsion, motor excitement is still present.

There are good reasons for giving a prophylactic injection of neostigmine in every case, irrespective of the degree of curarisation. Even after apparently moderate curarisation a convulsion may be followed by inhibition of respiratory movements and even by respiratory paralysis. Immediately after a convulsion it is at first impossible to differentiate between respiratory paralysis and reflex asphyxia. Since several minutes may elapse before intravenous neostigmine takes effect delay here is a serious disadvantage.

The following method of giving neostigmine and curare before inducing a convulsion is comparatively free from risk:

The curare having been injected into a vein in the usual way, the needle is left in position while another syringe, containing neostigmine 1 mg., is attached to it. A pneumatic bandage (such as is used in estimating blood-pressure) previously placed proximal to the site of injection is now inflated to a pressure exceeding arterial blood-pressure—e.g., 250 mm. Hg

The neostigmine is now injected into the vein, and the needle is removed without the bandage being deflated. Slight pressure on the site of injection and later the application of surgical tape prevent hæmorrhage from the vein. As soon as a major convulsion starts, the bandage is promptly deflated. The technique is quite simple and hardly increases the treatment time.

The latent period before the action of neostigmine is appreciable is $^1/_2$–$1^1/_2$ minutes from the end of the convulsion, when the restricted movements of the thorax will be seen to become completely free in the course of 10–15 seconds. The diarrhœa and nausea often associated with neostigmine therapy and occurring during the two hours immediately after the treatment may in most cases be effectively prevented with 0·5–1 mg. of atropine sulphate.

The peripheral circulation is apt to be deficient both during and after a major convulsion with, inter alia, a rise in venous pressure.[1 2] To investigate whether this might seriously delay the effect of the injected neostigmine I have carried out circulation tests with fluorescein; 2 ml. of 10% sodium fluorescein was added to the neostigmine. The pneumatic bandage was deflated at the onset of a major fit, and the fluorescein could be shown with Wood's glass in the conjunctivæ in every one of 30 patients before the end of the attack.

At my suggestion treatment since August, 1948, at the department of psychiatry, South Hospital, Stockholm, has been along the following lines.

---

1. Altschule, M. D., Tillotson, K. J. *Arch. Neurol. Psychiat.* 194 59, 469.
2. Silfverskiöld, B. P., Amark, C. *Acta med. scand.* 1943, 113, 191

ll patients treated with electroconvulsions and curare receive itine intravenous neostigmine. No patient is given more n 1 ml. of *d*-tubocurarine (Squibb) per 20 kg. of body-ight. For the first treatment all patients receive this dose s 0·5 ml. With this dosage no appreciable decrease is as ule noted in the force of muscular contractions during a nvulsion, but in ergograph test without E.C.T. the curare ect is clearly demonstrable.[3]

On systematic radiography we have seen only one nor vertebral fracture among 80 cases treated up to nuary, 1949.

To exclude cases of incipient myasthenia gravis ery patient is subjected to ergograph tests [3] before dergoing the treatment.

Division of Psychiatry,
South Hospital,
Stockholm.

TEACHING OF PUBLIC HEALTH

SIR,—I am much obliged to Prof. A. V. Neale for his tter in your issue of May 27 (p. 1019) with which I am complete agreement. The comment I made in the port to which he refers was :

> "It is gratifying to us to feel that the course for the diploma in public health is broad and liberal enough to attract students for its own sake, and its impress upon their colleagues from overseas affords us special pleasure."

his is quite consistent with our feeling of disappointment hat the *absolute* number of students entering the public ealth service in this country is so small. We expressed atisfaction at the relative composition of recent diploma lasses and hoped that it would be repeated in the years o come.

In my inaugural address in 1944 I said :

> "In my view the primary aim of a school or university department of hygiene is to make good general practitioners in health ; to send forth keen, competent men and women with a high sense of their calling and a scientific outlook."

It is our aim today to make the D.P.H. course a good ll-round training for general practitioners of medicine, nd we do indeed lay special stress, through seminars and field studies, on the epidemiologies of the home, the factory and workplace, the school, and the hospital. Two of our four full-time medical teachers are general practitioners of long experience, and the younger members of our staff hold part-time appointments in undergraduate schools.

The University of London has offered part-time teaching for the D.P.H. for many years, but no applications have been received. I myself was a part-time student, but found it very difficult to fit in the course with the calls and distractions of general practice. Our students come as a rule with fellowships or leave of absence for a year, or with a personal determination to throw themselves wholly into the work. They learn a great deal from one another in the course of morning coffee, lunch, or tea, as well as in the library and in the uncharted home, industrial, and hospital visits which they arrange as members of seminar groups. There is something in a whole-time course that knits them together in friendship and common purpose, and I should be sorry to lose the social and educational value of such an arrangement. All the same, we should be happy to coöperate with one or more other universities in organising part-time teaching, and we have in fact begun to discuss possible methods of adjustment.

I cannot imagine any more fascinating job than teaching public health at the present time : we are constantly experimenting and making mistakes and laughing about them and trying to do better. The main point, however, is that the students are our partners.

London School of Hygiene and
Tropical Medicine, Keppel Street, W.C.1.

J. M. MACKINTOSH.

Parliament

Medical Bill

IN the House of Lords on May 23 the Medical Bill was read the third time and passed.

QUESTION TIME

Certificates for Sickness Benefit

Mr. READER HARRIS asked the Minister of National Insurance when she issued her directive to branch offices instructing them that a claimant might establish title to sickness benefit by furnishing certificates signed by a person other than a registered medical practitioner, such as an osteopath, Christian Science healer or dentist : by what power such a directive was issued ; and how many sickness claims had been paid on the evidence of certificates issued by persons other than registered medical practitioners.—Dr. EDITH SUMMERSKILL replied : The National Insurance (Medical Certification) Regulations, 1948, require all claimants for sickness benefit to submit evidence of their incapacity. While this evidence normally includes a medical certificate, the statutory adjudicating authorities can take into consideration alternative evidence of incapacity if they think fit. I have no power to issue directions to these authorities. The information asked for in the last part of the question is not available, but the numbers are believed to be very small.

Mr. HARRIS : Is the Minister satisfied that certificates should be accepted from faith healers, herbalists, and other persons over whom control must necessarily be very vague, and is she herself, as a registered medical practitioner, satisfied with a state of affairs whereby the Willesden Institute of Natural Healing can tout for business by issuing circulars stating that certificates are available for National Insurance purposes ?—Dr. SUMMERSKILL : This method of determining incapacity has been operating for nearly 40 years, and if the hon. gentleman was a little older he would remember the sect called the Peculiar People who have a religious objection to doctors, and who have, in fact, formed their own approved society. I am quite aware of the fact that this right which people have of exercising conscientious objection, and which we believe it is right for them to have, may be abused, but I can assure the hon. gentleman that we are keeping a careful eye on the matter and that we have certain safeguards. We have sick visitors and also regional medical officers who can be called in for further medical examinations. Mr. HARRIS : Does not the Minister draw some distinction between public funds and the funds of an approved society which were not public funds before ?—Dr. SUMMERSKILL : Really, the hon. gentleman is displaying appalling ignorance. Does he not know that, before 1948, these approved societies used both public funds and private funds ?

Mr. RICHARD EWART : Is the Minister aware that her reply will give great satisfaction to thousands of people in this country who have for many years exercised this right of freedom of choice in determining what type of treatment they should take when sick, and that her devastating reply to the prejudices of the hon. Member opposite will be gratefully received ?

National Assistance

In answer to a question Dr. SUMMERSKILL stated that at the end of April, 1950, regular weekly grants of National Assistance were being paid to 1,192,000 persons.

Sanatorium Waiting-lists

In answer to a question, Mr. A. BEVAN stated that approximately 11,000 people suffering from tuberculosis were waiting for beds in sanatoriums.

Under-doctored Areas

Mr. SOMERVILLE HASTINGS asked the Minister whether it was necessary for a doctor to provide himself with a surgery as a first preliminary to submitting his name for inclusion in the medical list as a principal in an under-doctored area.—Mr. BEVAN replied : It is not necessary for a doctor to have a surgery before he applies for inclusion, but the Medical Practices Committee may make the granting of an application conditional upon his acquiring one within a specified time.

Cost of Drugs

Mr. HASTINGS asked the Minister what was the average annual cost of drugs per insured person under the National

Health Insurance Act before July 5, 1948; and how this compared with that of drugs ordered by general practitioners for their patients under the National Health Service Act.—Mr. BEVAN replied: The average annual cost of providing pharmaceutical services per insured person in the 12 months ended July 5, 1948, was 6*s.* 8*d.* In the 12 months ended March 31, 1950, the average cost per head of the civilian population of providing such services was 14*s.* 7*d.*

Staff Attendance Book

Surgeon Lieut.-Commander R. F. B. BENNETT asked the Minister under what authority a book was to be placed in the Maudsley Hospital, S.E.5; for the recording of the times of attendance of full-time medical staff.—Mr. BEVAN replied: I understand that the board of governors have under consideration arrangements for recording not the times but the fact of attendance. The matter is one within the discretion of the board of governors.

Notification of German Measles

Sir W. WAKEFIELD asked the Minister what steps had been taken to publicise the dangers of german measles in early pregnancy, and the need to notify this illness in order to minimise deafness at birth in children.—Mr. BEVAN: The evidence of danger so far available is indefinite, and an inquiry on a national basis is about to be made.

Obituary

LEONARD GRAHAM BROWN

M.C., M.A., D.M. OXFD, F.R.C.S.

Mr. L. Graham Brown, senior surgeon to the ear, nose, and throat department of Charing Cross Hospital, died in London on May 23.

He was born at Brisbane in 1888, the second son of the late John Graham Brown, who came of an Ulster family. Already in his school days at Brisbane Grammar School he was an all-round athlete. Besides rowing, swimming, running, and shooting he was junior champion gymnast of Queensland in 1905, and in 1908 he played rugby for Queensland against an Anglo-Welsh team led by A. F. Harding. Soon after this, with a Rhodes scholarship, he began his studies at Balliol College, Oxford. In 1910 he was awarded his rugby blue and in 1912 he captained the Oxford XV. As a forward he played eighteen times for England between 1911 and 1922, when he was captain. While at Oxford he also rowed for Balliol.

[Lafayette

In 1912 he took his B.A. with honours in natural science, and three years later he qualified from the London Hospital. During the 1914–18 war he served with the R.A.M.C., rising to the rank of lieut.-colonel. In 1918 he was awarded the M.C. and mentioned in despatches. After demobilisation he took his B.M. in 1919, his D.M. the following year, and the F.R.C.S. in 1923. He held an aural registrarship at the London Hospital before he settled in consultant practice. In due course he was appointed to the staff of Charing Cross Hospital and of the North Middlesex Hospital. He examined for the D.L.O. for the Royal College of Surgeons. For his presidential address to the section of otology of the Royal Society of Medicine in 1944 he chose as his subject Twenty-Five Years' Practice in Mastoid Surgery, and he also contributed the chapter on diseases of the ear to *Hutchison's Index of Treatment* and a monograph on inflammations of the external ear and external auditory meatus to *Nelson's Medicine of the Ear.*

After ten years' service as vice-president of the Rugby Football Union he was elected president in 1948 and he held office till 1949. During the late war he was medical superintendent of Charing Cross Hospital.

E. D. D. D. writes: "Known as Bruno to a large circle of his friends, he was the best of colleagues, calm, courteous, never angry; and he accepted any adv with a smile. His imperturbable, equable temperam with a complete absence of thrust, and perhaps fact that he put on some weight after he gave 'rugger,' was interpreted by a few as apathy. whatever Bruno undertook he did well and ac success in his own quiet way. His mastoid surgery *conservative and original, easily and skilfully* perfo He excelled at his successful enucleation of tonsils children by the reverse guillotine. His dexterity celerity in this operation, which so many find to learn, was remarkable. A day's golf, or ski-ing in crystal-clear Alps, with Bruno was a joy and a de He was a natural leader, inspiring confidence, and men followed him. As a colleague and loyal friend was easy to obtain his complete understanding cordial collaboration. He was a great gentleman who be remembered for many years."

In 1915 Mr. Graham Brown married Margaret Jane Menzies of Edinburgh, and they had two daughters.

EDGAR WILLIAM TODD

M.A., M.D. CAMB., D.P.H.

Dr. E. W. Todd, who died in Jamaica on May 11, at the age of 60, had been acting director of the London County Council antitoxin establishment at Sutton until he went to the United States in 1946.

From King's School, Canterbury, he went to Trinity College, Cambridge, and then to St. Thomas's Hospital graduating B.A. in 1911. After doing Red Cross work in the Balkan War he took the Conjoint diploma in 1915; and he served in the Royal Navy as temporary surgeon-lieutenant until 1919, spending much time in Arctic waters. He obtained the D.P.H. of Durham University in 1919, and he graduated M.B. the *following* year. In 1923 he proceeded to his M.D. degree. After holding house-appointments at the Norwich and Norfolk General Hospital, St. Thomas's Hospital, and St. Bartholomew's Hospital, he began research work in the inoculation department at St. Mary's Hospital. The stimulus of contact with Wright, Fleming, Freeman, Colebrook, Fry, Hare, and their colleagues remained with him and he spent the rest of his life on bacteriological research.

In 1927 he went to the Rockefeller Institute with a medical fellowship. Here again the stimulus of laboratory colleagues, especially Mrs. Lancefield, Avery, and Swift, proved lasting, and Todd's interest from that time wavered little from hæmolytic streptococcal infections, in particular rheumatic fever. When, in 1930, he was appointed bacteriologist to the L.C.C. antitoxin establishment, then situated at the Belmont laboratories, Todd settled down to long days of work at the laboratory bench, barely finding time to eat sandwiches at midday. During this period the two hæmolysins produced in hæmolytic streptococcus cultures, one oxygen-labile and the other oxygen-stable, were characterised and the titration of antistreptolysin in patients' blood-sera was developed as an aid to the diagnosis of streptococcal infections, particularly in rheumatic fever.

When the new laboratories at Carshalton were completed, and the director, *Dr. R. G. White,* retired, resources had to be devoted to war-time requirements. Todd found it increasingly difficult to give his whole time to laboratory work, and at the end of the war he returned to New York to spend a year at the Rockefeller Institute. When Dr. Alvin Coburn started the Rheumatic Fever Research Institute in Chicago, Todd joined him; but while on holiday symptoms of his *illness* appeared and he returned with his wife to Jamaica, where he remained, until his death, except for a brief visit to the U.S.A. for medical treatment.

L. F. H. writes: "Edgar Todd had a single-minded devotion to research and few recreations except walking and peaceful weekends at a tiny cottage at Newdigate in Surrey. Although he was a member of the Pathological Society, of the section of pathology of the Royal Society of Medicine, and of the Medical Research Club, he could not be persuaded to read papers in public. He was my colleague for 16 years and I can only endorse the regret of *Sir Allen Daley,* who writes, 'It is a great tragedy that he has been cut off at the height of his career.'"

DR. B. A. PETERS

M. writes: "From his school days Dr. Peters was nensely interested in chemistry, and he carried this erest with him throughout his life. In consequence applied a wealth of biochemical knowledge to medical blems and he wrote many articles from a biochemical nt of view. His knowledge of this specialty was far d away above the head of the average medical man d often, in his enthusiasm, Dr. Peters assumed owledge in others which did not necessarily exist. r many years he was a member of the Biochemical ciety. Living during the greatest period of advance the treatment of infectious diseases, Dr. Peters proached all the problems with scientific care, and, as he s always willing to apply experimental tests, he wrote any useful papers on such subjects as diphtheria, arlet fever, gastro-enteritis, erysipelas, and immunisaon, on which he held sound practical views.

"As a man, Dr. Peters was consistently upright. friend of children, he took the greatest pleasure in eir company; with adults he tended to be shy, but s friendship, once gained, was something to depend n and to be valued. He belonged to the race of great inical teachers, and his knowledge of humanity, medine, biochemistry, birds, and flowers can ill be spared. r. Peters had become an institution, so benevolent and ise, that it is unbelievable that his advice is no longer vailable."

We regret to announce the death of Prof. FRANZ OLHARD, the distinguished clinical nephrologist, of rankfort-on-Maine.

Appointments

BRAND, T. A., M.D. Brist., D.C.H.: consultant pædiatrician, Newport and East Monmouthshire and North Monmouthshire hospital groups.

COUCH, A. H. C., M.D. Lond., M.R.C.P., D.C.H.: asst. chest physician (senior registrar), East Suffolk and Ipswich area.

RICHARDSON, H. J., L.R.C.P.E., D.A.: consultant anæsthetist, Peterborough area.

ROSS, N. A., M.B. Lond., D.P.H.: consultant venereologist, Stamford, Peterborough, and King's-Lynn area.

WALKER, A. L., M.A., M.B. Camb., F.R.C.S., F.R.C.O.G.: consultant gynæcological surgeon, Wembley Hospital.

Appointed Factory Doctors:

ELLIS, E. A., B.A., M.B. Dubl.: Great Yarmouth district.

HARDING, G. I., M.R.C.S., D.P.H.: Staines district.

MILLER, H. D., M.B. Glasg.: Jarrow district.

ROSS, W. C., L.R.C.P.E.: Tain district.

Births, Marriages, and Deaths

BIRTHS

CANTRELL.—On May 19, the wife of Dr. G. L. Cantrell—a daughter.

HORDER.—On May 16, in London, the wife of Dr. John Horder—a son.

JACKSON.—On May 22, to Dr. Shirley Jackson (née Williams), wife of Dr. R. H. Jackson—a son.

JOHNSON.—On May 22, in London, the wife of Dr. T. E. Johnson—a daughter.

RAMPLING.—On May 24, in Manchester, the wife of Dr. A. E. Rampling—a son.

STOTT.—On May 15, at Nakuru, Kenya, the wife of Dr. Hugh Stott—a daughter.

TURTLE.—On May 19, the wife of Dr. J. B. Turtle—a son.

MARRIAGES

BROOK—SENIOR.—On May 18, in Manchester, Alexis Brook, M.B., to Maureen Senior.

REES—TARVER.—On May 20, at Wing, Bucks, Harland Rees, F.R.C.S., to Helen Marie Tarver.

DEATHS

BROWN.—On May 23, in London, Leonard Graham Brown, M.C., M.A., D.M. Oxfd, F.R.C.S., aged 62.

BROWN.—On May 21, in Edinburgh, Donald Thomas Alexander Brown, M.S. Lond., F.R.C.S.E., aged 28.

EEMAN.—In February, at Amersham, Peter Derek Eeman, M.B. Camb.

PADDLE.—On May 24, at Botleys Park, Chertsey, Kenneth Cecil Lawrence Paddle, M.C., M.R.C.S., D.P.M.

PATERSON.—On May 23, at Ipswich, Arthur William Paterson, M.B. Aberd., aged 79.

SNOWDEN.—On May 20, at Bournemouth, Arthur de Winton Snowden, C.B.E., M.A., M.D. Camb.

TOWNLEY.—On May 24, in Manchester, Herbert Townley, M.B. Manc.

WALLA.—On May 23, in London, Sohrab Hodi Walla, L.R.C.P.E., D.P.H., aged 65.

WELPLY.—On May 21, at Welwyn Garden City, Gilman Chinnery Welply, M.R.C.S., aged 41.

Notes and News

PROPHYLACTIC INOCULATION AND POLIOMYELITIS

AT a meeting on May 4, the London Medical Service Committee considered a parent's complaint that a practitioner had been negligent in inoculating an infant boy who was later found to have poliomyelitis. The complainant said that on Dec. 6, 1949, he took his child to this doctor for inoculation against diphtheria. The doctor gave the injection, stating that immunisation against whooping-cough was also included. On Dec. 24, the child appeared to be unwell. He later began to develop the symptoms of a cold, together with vomiting and diarrhœa; and his parents took him to the doctor, who expressed the opinion that the boy was suffering from bronchitis and prescribed medicine. On Jan. 6, the parents took the baby for the second injection against diphtheria. They informed the doctor that the child still had the symptoms of a cold, and inquired whether it would be in order for the injection to be given. The practitioner replied that it would; and he gave the injection into the boy's left buttock. The child continued to have diarrhœa and the symptoms of a cold; and he was attended a number of times by the practitioner and his assistant. On Jan. 23, the complainant, after consulting a textbook on child care, formed the opinion that the symptoms were consistent with poliomyelitis. That morning the practitioner's assistant visited the patient; later the assistant and the principal saw the patient together; and it was arranged for him to be admitted to hospital, where he was found to have poliomyelitis. From a conversation which he had with a doctor at the hospital, the complainant concluded that his son's condition resulted from the whooping-cough immunisation. Further inquiries strengthened this conviction; and he decided that the practitioner should have been warned by the child's symptoms after the first injection and should have refrained from administering the second. He contended that the practitioner's action in proceeding with the second injection amounted to negligence.

The practitioner testified that when giving both the first and the second injections he was satisfied that, although the child had a slight cold, there was nothing in his condition to contra-indicate their administration. He was confident that these injections had not caused the poliomyelitis.

The complainant informed the committee that the child was likely to be permanently affected in the left leg. The committee reported to the executive council that "his understandably intense feeling on the subject has led him to make inquiries into the technical aspects of immunisation, and we found on questioning him that he has obtained advice from an organisation which is opposed to vaccination and like treatment and has accordingly formed views which are not in conformity with the body of medical opinion." The committee was satisfied that the doctor had exercised due care and attention.

University of Oxford

The Osler memorial medal has been awarded to Sir Ernest Kennaway, D.M., F.R.S., honorary fellow of New College.

University of London

The governing body of the British Postgraduate Medical Federation has awarded postgraduate travelling fellowships for 1950–51, tenable for one year, to: G. L. W. Bonney, M.S., F.R.C.S., of the Institute of Orthopædics (orthopædic surgery, Manchester and Scandinavia); P. J. Hare, M.B., M.R.C.P., of University College Hospital (dermatology, France and Switzerland); H. O. Jones, M.S., F.R.C.S., of King's College Hospital (thoracic surgery, Leeds and Scandinavia); J. S. Pegum, M.B., M.R.C.P., of Guy's Hospital (dermatology, France and Switzerland); D. J. Robertson, B.S., F.R.C.S., of St. Bartholomew's Hospital (vascular surgery, Edinburgh and Scandinavia).

University of Liverpool

At recent examinations for the D.T.M. & H., the following were successful:

B. O. Barry, T. Briceno-Maaz, L. H. Chandler, C-S. Chou, E. W. R. Fairley, D. E. Freeman, J. B. Henderson, L. H. Holroyd, A. W. Iljon, C-L. Lee, T. P. Niyogi, A. B. Raper, D. K. Sen, K. C. Trivedi, A. F. Tuboku-Metzger, C. E. M. Wenyon.

Dr. L. H. Holroyd has been recommended for the Milne medal in tropical medicine, and Dr. A. B. Raper for the Warrington Yorke medal in tropical hygiene.

Royal College of Physicians of London

On Tuesday and Thursday, June 20 and 22, at 5 P.M., Prof. J. H. Dible will deliver the Humphry Davy Rolleston lectures at the college, Pall Mall East, S.W.1. He is to speak on Degeneration, Necrosis, and Fibrosis in the Liver.

Royal College of Obstetricians and Gynæcologists

At a meeting of the college held on May 20, with Prof. Hilda Lloyd, the president, in the chair, the following were elected to the council:

Dugald Baird, Aberdeen, W. E. Barnie-Adshead, Birmingham, A. M. Claye, Leeds, Victor Lack, London, Gilbert Strachan, Cardiff, R. C. Thomas, Croydon (as representatives of the fellows); A. M. Sutherland, Glasgow, Stanley Way, Newcastle upon Tyne (as representatives of the members); W. A. G. Bauld, Montreal, Sir William Gilliatt, London, C. D. Read, London, B. H. Swift, Adelaide, Leslie Williams, London (coöpted for the ensuing year).

The following were admitted to the fellowship:

H. G. E. Arthure, Elinor F. E. Black, J. H. Boyd, Robert Everett, P. J. Ganner, Kathleen M. D. Harding, F. J. Haydon, K. A. K. Hudson, T. I. Hughes, B. L. Jeaffreson, R. W. Knowlton, Joyce Morgan, J. S. Quin, D. A. O'C. Quinlan, L. M. Snaith, G. R. Stoneham, Margaret Moore White.

The following were admitted to the membership:

J. A. Bentham, D. W. Briggs, H. McK. [illegible] Choul [illegible] Reginald Cutt [illegible] H. J. [illegible] Harper, W. F. I [illegible] Pullat [illegible] Love, Sarah-Macaskill, A. S. Majury, A. T. [illegible], J. G. Napier, F. P. Pigott, J. H. McK. Pinkerton, C. C. Pre[illegible] jannayagam, T. M. Roulston, J. H. Rout [illegible] inha, Zubaida Haji Yousof Sobani, W. A. S [illegible] George Winchester.

International Exhibition of Medical Photography

At 4 P.M., on Saturday, June 10, Sir Heneage Ogilvie will open this exhibition, which is being held by the medical group of the Royal Photographic Society, at 11, Chandos Street, London, W.1, from June 12 to 24. Opening hours are 10 A.M. to 5 P.M. (Wednesdays 10 A.M. to 8 P.M.).

Review of Maternity Benefits

The National Insurance Advisory Committee, under the chairmanship of Sir Will Spens, are reviewing the payments for maternity now made under the insurance scheme, and considering whether any improvements can be made in the allowances provided under the 1948 scheme without adding to the present liability of the National Insurance Fund for maternity. Organisations and persons who wish to submit representations should write to the secretary of the committee, 30, Euston Square, London, N.W.1, before Thursday, Aug. 31, 1950.

At present the National In[illegible]'s are: a maternity grant of £4 with an [illegible] £1 a week during the four weeks after th[illegible]; or, for women normally in employment, a maternity grant of £4 with a maternity allowance of 36s. a week starting six weeks before the week in which the baby is expected and continuing until six weeks after—that is, usually for 13 weeks (about £27 in all). The grant [illegible] are paid subject to contribution [illegible] ontributions may have been paid by [illegible] Payment of maternity allowance [illegible] ord of employment and credits for weeks of unemployment or sickness in the year before the allowance begins.

North-West Metropolitan Regional Hospital Board

At a meeting on May 16, the board considered what action should be taken in response to a recommendation by the local medical committee for the County of London that laboratory facilities be made directly available to general practitioners. The board agreed that:

1. Hospit[illegible]s be asked to state: (*a*) the hospitals th[illegible]ndertake pathological investigations for [illegible]. (*b*) the additional staff and accommodation that would be required at those hospitals which cannot at present undertake the work.

2. The service should cover only the simplest of tests, these to be determined *after consultation with the pathologist or his assistant.*

3. Since the Public Health Laboratory Service is also setting up a scheme whereby much bacteriological work could be done for general practitioners, some correlation between the two services should be made to prevent duplication.

The board was informed that a protest had been made against its decision to advertise the vacant post of pædiatrician at the Royal London Homœopathic Hospital without stating in the advertisement that it was necessary for candidates to hold a qualification in homœopathy (see *Lancet*, May 6, p. 888). The Ministry of Health had confirmed that an undertaking was given that the character of this hospital —if incorporated in the National Health Service—would not be changed; and the board decided to require candidates for the appointment to be members or fellows of the Faculty of Homœopathy.

Withdrawal from W.H.O.

Hungary has announced its intention to withdraw from World Health Organisation.

The Old Westminster Hospital

Demolition of the old Westminster Hospital, opposi Westminster Abbey, is now going ahead rapidly. The site, being cleared for the erection of the new Colonial Office. B for the war the old hospital would have been pulled do earlier; *during the war it was used as a hostel for Servicem*

The Child and His Environment

This has been chosen as the main subject for discu at the annual conference which the National Associa for Maternity and Child Welfare are holding at F House, Euston Road, London, N.W.1, from June 28 to The speakers will include Dr. Fraser Roberts, Dr. Eman Miller, Prof. R. S. Illingworth, Dr. John Bowlby, and D Dorothy Makepeace. Further particulars may be had fro the secretary of the association, 5, Tavistock Place, Lond W.C.1.

Nurses and Midwives Whitley Council

The joint public-health and midwives standing committe of the Nurses and Midwives Whitley Council have agre with the management side on new salary scales for publ health nurses and domiciliary nurses and midwives, in th light of the Industrial Court's recent award raising the salari of non-resident district nurses with district training from scale of £300–£405 to £340–£465. The grades covered b the new agreement include health and tuberculosis visitor school nurses, and district nurses and midwives. Detai will not be available immediately, but the new scales wi take effect from Feb. 1, 1949.

Diary of the Week

JUNE 4 TO 10

Monday, 5th

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.1
5 P.M. Dr. Michael Kremer: Frontal Lobe Syndromes.
INSTITUTE OF OPHTHALMOLOGY, Judd Street, W.C.1
5.30 P.M. Dr. Macdonald Critchley: Problem of Awarene and Non-awareness of Visual Field Defects.

Tuesday, 6th

ROYAL COLLEGE OF PHYSICIANS
5 P.M. Dr. Evan Jones: Hypertension.
ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2
5 P.M. Mr. F. S. Gorrill: Anatomy and Physiology of the Spleen. (Arnott demonstration.)
INSTITUTE OF DERMATOLOGY, Lisle Street, W.C.2
5 P.M. Dr. I. Muende: Pigmentary Conditions of the Skin.
UNIVERSITY OF EDINBURGH
5 P.M. (University New Buildings, Teviot Place.) Mr. Daniel Bovet, D.SC. (Rome): The Discovery of the Antihistamines. (Cameron prize lecture.)

Wednesday, 7th

WEST LONDON HOSPITAL MEDICAL SCHOOL
8.30 P.M. (11, Chandos Street, W.1.) Sir James Learmonth: Surgery of the Sympathetic Nervous System. (Alex Simpson Smith lecture.)
INSTITUTE OF PSYCHIATRY, Maudsley Hospital, S.E.5
4.30 P.M. Dr. E. Stengel: Psychiatry lecture-demonstration.
INSTITUTE OF OPHTHALMOLOGY
5.30 P.M. Miss K. Tansley, D.SC.: Electroretinography.
UNIVERSITY OF EDINBURGH
5 P.M. Prof. H. M. Evans (University of California): Hormones of the Anterior Hypophysis.

Thursday, 8th

ROYAL COLLEGE OF PHYSICIANS
5 P.M. Prof. N. B. Capon: Urinary Infections in Childhood.
UNIVERSITY OF LONDON
5.30 P.M. (King's College, Strand, W.C.2.) Prof. L. S. Ston (Yale University): Development of Normal and Abnorma Vision Observed in Animals with Transplanted Eyes.
INSTITUTE OF NEUROLOGY, National Hospital, Queen Square, W.C.1
5 P.M. Sir James Learmonth: Combined Neurovascular Lesion of the Extremities.
INSTITUTE OF DERMATOLOGY
5 P.M. Dr. H. Gordon: Lupus Erythematosus.
HONYMAN GILLESPIE LECTURE
5 P.M. (Edinburgh University New Buildings.) Dr. G. A. Grant Peterkin: Drug Rashes.

Friday, 9th

THE GENERAL PATHOLOGY OF VIRUS INFECTIONS*

F. M. BURNET
M.D.Melb., Hon. Sc.D.Camb., F.R.S.
DIRECTOR OF THE WALTER AND ELIZA HALL INSTITUTE OF MEDICAL RESEARCH; PROFESSOR OF EXPERIMENTAL MEDICINE IN THE UNIVERSITY OF MELBOURNE

THE general pathology of virus infection is clearly too vast a subject to be covered in a single lecture. I have chosen it because I feel that there is scope for the formulation of a simple framework of ideas which may make it easier to understand the situation in any particular virus disease. Rightly or wrongly I have the impression that many people have considerable difficulty in seeing any common features in the pathology or immunology of measles, influenza, and herpes simplex—to take three diseases familiar to everyone. From these or other examples of human virus infections one can see diseases of short or long incubation period, some that confer lifelong subsequent immunity, some that persist like trachoma or recur from within like herpes simplex, and some that show short-lasting immunity like the respiratory infections. My task is to look for the common factors, if any, within this multiform behaviour of human virus diseases.

There is no universally accepted definition of a virus; the one I prefer is that a virus is a parasitic micro-organism considerably smaller than most bacteria, which is capable of multiplication only within living susceptible host cells. This definition is elastic enough to allow one to include or exclude the rickettsiæ and psittacosis-type organisms as circumstances require! As they appear to be intermediates between bacteria and "true" viruses, one must expect to find it necessary to seek analogies sometimes in one group, sometimes in the other.

The time has passed, at least in the case of the animal viruses, when it was necessary to withhold the term organism from a virus. It is now some years since anyone has seriously spoken of viruses as non-living protein molecules. The crux of the definition is the limitation of virus growth to the interior of the susceptible cell. This restriction determines the general form of the techniques that must be used in experimental virology. Instead of the bacteriological medium in test-tube or petri dish we have the mouse brain or the cavities of the developing chick embryo as the standard substrates for virus multiplication in the laboratory. The restriction to intracellular growth also automatically determines the framework for our discussion of the general pathology of virus infection. Any typical virus disease—influenza, yellow fever, smallpox, or what not—is initiated in nature by a very small inoculum, perhaps involving in the first instance one or two cells only. If the disease develops, very many more cells are involved, symptoms appear, and the patient dies or recovers.

We can look at that process at two levels: (1) as it involves the individual cell; and (2) as it concerns the susceptible cells of the body as a whole.

1. At the microscopic (cellular) level we have to consider:

(*a*) The entry of virus into the cell.
(*b*) The process of intracellular multiplication.
(*c*) Liberation of virus and cell damage or disintegration.

2. At the macroscopic level we have:

(*d*) The process by which infection spreads from the site of initiation to the other susceptible cells.
(*e*) The process by which infection is overcome.

I shall necessarily have to treat each of these phases in summary and rather dogmatic fashion, but somehow I do not think that I shall leave any of you with the feeling that all is now understood about the pathology of virus infection. I shall be disappointed in fact if here and there I cannot pass over to you some of my own enthusiasm for the idea that in the study of virus action on cells and organisms we have one of the most potent tools for the advancement of fundamental biology. There is an enormous field to be explored within the living cell, and perhaps I could express my own attitude to virus research by saying that we start from clinical medicine—from the patient with influenza, smallpox, or herpes—and pass almost at once to the fundamental biological problems of reproduction, mutation, and survival, in their most generalised form. In the end we shall, I hope, return with ideas and techniques that are directly applicable to human benefit—or at least to the satisfaction of human desires.

Virus Entry into the Cell

To multiply within a cell, the infecting virus particle must pass through the cell surface into the interior. In very many instances this seems to present no difficulty. A wide range of cells, particularly those of mesenchymal origin, have the potential capacity to take small foreign particles into their substances. Many viruses too can multiply within a wide range of cell types including macrophages. At the present time it is reasonable to assume that for those viruses without very marked tissue specificity, and especially for those that are introduced into the body through a traumatised area, no specific mechanism for passage through the cell surface is necessary. Sometimes the trauma required is the bite of a mosquito, as in yellow fever; viruses like herpes simplex and lymphogranuloma venereum probably enter through slight abrasions of mucous surfaces. Such viruses will not be further discussed in this section, but I am by no means certain that a new approach in the future may not show that we are wrong in assuming that no special means exists by which the virus makes contact with and passes through the surface of cells particularly suitable for its multiplication. Biological phenomena have a habit of appearing simple until we find the appropriate tools to investigate them.

INTERACTIONS AT CELL SURFACE

In 1941 Hirst discovered a most effective tool for the study of the interaction of influenza virus and the cell surface, in the form of the hæmagglutination reaction. Many years previously, however, work in which I myself played a part showed that bacterial viruses had also specific relationships with the surfaces of the bacteria they infected, and that methods could be devised for the study of these relationships. From work on these two groups of viruses what is really no more than a probable provisional generalisation can be made—namely, that, when a virus must invade and infect a cell through an intact surface exposed to the environment, a special mechanism for this purpose is usually demonstrable. So far the great bulk of investigation has been done with viruses of the influenza group, including mumps and Newcastle disease of fowls, and in this lecture I shall discuss only this group.

At the Walter and Eliza Hall Institute my colleagues and I have spent most of the last four or five years in work arising out of Hirst's discovery that influenza virus will agglutinate red cells of several species. Similar work has been going on elsewhere, and from the combined effort a fairly clear picture has emerged of the process by which this virus becomes attached to and enters the cells susceptible to its action—i.e., the cells lining the respiratory tract.

Royal College of Physicians of London

On Tuesday and Thursday, June 20 and 22, at 5 P.M., Prof. J. H. Dible will deliver the Humphry Davy Rolleston lectures at the college, Pall Mall East, S.W.1. He is to speak on Degeneration, Necrosis, and Fibrosis in the Liver.

Royal College of Obstetricians and Gynæcologists

At a meeting of the college held on May 20, with Prof. Hilda Lloyd, the president, in the chair, the following were elected to the council:

Dugald Baird, Aberdeen, W. E. Barnie-Adshead, Birmingham, A. M. Claye, Leeds, Victor Lack, London, Gilbert Strachan, Cardiff, R. C. Thomas, Croydon (as representatives of the fellows); A. M. Sutherland, Glasgow, Stanley Way, Newcastle upon Tyne (as representatives of the members); W. A. G. Bauld, Montreal, Sir William Gilliatt, London, C. D. Read, London, B. H. Swift, Adelaide, Leslie Williams, London (coöpted for the ensuing year).

The following were admitted to the fellowship:

H. G. E. Arthure, Elinor F. E. Black, J. H. Boyd, Robert Everett, P. J. Ganner, Kathleen M. D. Harding, F. J. Hayden, K. A. K. Hudson, T. I. Hughes, B. L. Jeaffreson, R. W. Knowlton, Joyce Morgan, J. S. Quin, D. A. O'C. Quinlan, L. M. Snaith, G. R. Stoneham, Margaret Moore White.

The following were admitted to the membership:

J. A. Bentham, D. W. Briggs, H. McK. Carey, Florence J. G. Chouler, Robert Crawford, Reginald Cutts, M. S. Ellensweig, H. J. Fisher, Elizabeth M. Harper, W. F. Harper, J. S. Hesketh, Pullat Kalyanikutty, J. A. Love, Sarah Macaskill, A. S. Majury, A. T. Marshall, J. D. Martin, J. G. Napier, F. P. Pigott, J. H. McK. Pinkerton, C. C. Pretorius, Sangarapillai Rajanayagam, T. M. Roulston, J. H. Routledge, Aroon Chandra Sinha, Zubaida Haji Yousof Sobani, W. A. Souter, Alexander Starritt, George Winchester.

International Exhibition of Medical Photography

At 4 P.M., on Saturday, June 10, Sir Heneage Ogilvie will open this exhibition, which is being held by the medical group of the Royal Photographic Society, at 11, Chandos Street, London, W.1, from June 12 to 24. Opening hours are 10 A.M. to 5 P.M. (Wednesdays 10 A.M. to 8 P.M.).

Review of Maternity Benefits

The National Insurance Advisory Committee, under the chairmanship of Sir Will Spens, are reviewing the payments for maternity now made under the insurance scheme, and considering whether any improvements can be made in the allowances provided under the 1948 scheme without adding to the present liability of the National Insurance Fund for maternity. Organisations and persons who wish to submit representations should write to the secretary of the committee, 30, Euston Square, London, N.W.1, before Thursday, Aug. 31, 1950.

At present the National Insurance maternity benefits are: a maternity grant of £4 with an attendance allowance of £1 a week during the four weeks after the baby is born (£8 in all); or, for women normally in employment, a maternity grant of £4 with a maternity allowance of 36*s*. a week starting six weeks before the week in which the baby is expected and continuing until six weeks after—that is, usually for 13 weeks (about £27 in all). The grant and the attendance allowance are paid subject to contribution conditions. The qualifying contributions may have been paid by either the husband or wife. Payment of maternity allowance depends on the woman's record of employment and credits for weeks of unemployment or sickness in the year before the allowance begins.

North-West Metropolitan Regional Hospital Board

At a meeting on May 16, the board considered what action should be taken in response to a recommendation by the local medical committee for the County of London that laboratory facilities be made directly available to general practitioners. The board agreed that:

1. Hospital management committees be asked to state: (*a*) the hospitals that are willing and able to undertake pathological investigations for practitioners immediately; (*b*) the additional staff and accommodation that would be required at those hospitals which cannot at present undertake the work.

2. The service should cover only the simplest of tests, these to be determined after consultation with the pathologist or his assistant.

3. Since the Public Health Laboratory Service is also setting up a scheme whereby much bacteriological work could be done for general practitioners, some correlation between the two services should be made to prevent duplication.

The board was informed that a protest had been made against its decision to advertise the vacant post of pædiatrician at the Royal London Homœopathic Hospital without stating in the advertisement that it was necessary for candidates to hold a qualification in homœopathy (see *Lancet*, May 6, p. 888). The Ministry of Health had confirmed that an undertaking was given that the character of this hospital —if incorporated in the National Health Service—would not be changed; and the board decided to require candidates for the appointment to be members or fellows of the Faculty of Homœopathy.

Withdrawal from W.H.O.

Hungary has announced its intention to withdraw from World Health Organisation.

The Old Westminster Hospital

Demolition of the old Westminster Hospital, opposite Westminster Abbey, is now going ahead rapidly. The site being cleared for the erection of the new Colonial Office. But for the war the old hospital would have been pulled down earlier; during the war it was used as a hostel for Servicemen.

The Child and *His Environment*

This has been chosen as the main subject for di at the annual conference which the National Assoc for Maternity and Child Welfare are holding at F House, Euston Road, London, N.W.1, from June 28 to The speakers will include Dr. Fraser Roberts, Dr. Emanuel Miller, Prof. R. S. Illingworth, Dr. John Bowlby, and Dr. Dorothy Makepeace. Further particulars may be had from the secretary of the association, 5, Tavistock Place, London, W.C.1.

Nurses and Midwives Whitley Council

The joint public-health and midwives standing committee of the Nurses and Midwives Whitley Council have agreed with the management side on new salary scales for public health nurses and domiciliary nurses and midwives, in the light of the Industrial Court's recent award raising the salaries of non-resident district nurses with district training from a scale of £300–£405 to £340–£465. The grades covered by the new agreement include health and tuberculosis visitors, school nurses, and district nurses and midwives. Details will not be available immediately, but the new scales will take effect from Feb. 1, 1949.

Diary of the Week

JUNE 4 TO 10

Monday, 5th

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.1
5 P.M. Dr. Michael Kremer: Frontal Lobe Syndromes.
INSTITUTE OF OPHTHALMOLOGY, Judd Street, W.C.1
5.30 P.M. Dr. Macdonald Critchley: Problem of Awareness and Non-awareness of Visual Field Defects.

Tuesday, 6th

ROYAL COLLEGE OF PHYSICIANS
5 P.M. Dr. Evan Jones: Hypertension.
ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2
5 P.M. Mr. F. S. Gorrill: Anatomy and Physiology of the Spleen. (Arnott demonstration.)

THE GENERAL PATHOLOGY OF VIRUS INFECTIONS *

F. M. BURNET

M.D.Melb., Hon. Sc.D.Camb., F.R.S.

RECTOR OF THE WALTER AND ELIZA HALL INSTITUTE OF EDICAL RESEARCH; PROFESSOR OF EXPERIMENTAL MEDICINE IN THE UNIVERSITY OF MELBOURNE

THE general pathology of virus infection is clearly so vast a subject to be covered in a single lecture. I ave chosen it because I feel that there is scope for the ormulation of a simple framework of ideas which may make it easier to understand the situation in any particular virus disease. Rightly or wrongly I have the mpression that many people have considerable difficulty n seeing any common features in the pathology or mmunology of measles, influenza, and herpes simplex—o take three diseases familiar to everyone. From these or other examples of human virus infections one can see diseases of short or long incubation period, some that confer lifelong subsequent immunity, some that persist like trachoma or recur from within like herpes simplex, and some that show short-lasting immunity like the respiratory infections. My task is to look for the common factors, if any, within this multiform behaviour of human virus diseases.

There is no universally accepted definition of a virus: the one I prefer is that a virus is a parasitic micro-organism considerably smaller than most bacteria, which is capable of multiplication only within living susceptible host cells. This definition is elastic enough to allow one to include or exclude the rickettsiæ and psittacosis-type organisms as circumstances require! As they appear to be intermediates between bacteria and "true" viruses, one must expect to find it necessary to seek analogies sometimes in one group, sometimes in the other.

The time has passed, at least in the case of the animal viruses, when it was necessary to withhold the term organism from a virus. It is now some years since anyone has seriously spoken of viruses as non-living protein molecules. The crux of the definition is the limitation of virus growth to the interior of the susceptible cell. This restriction determines the general form of the techniques that must be used in experimental virology. Instead of the bacteriological medium in test-tube or petri dish we have the mouse brain or the cavities of the developing chick embryo as the standard substrates for virus multiplication in the laboratory. The restriction to intracellular growth also automatically determines the framework for our discussion of the general pathology of virus infection. Any typical virus disease—influenza, yellow fever, smallpox, or what not—is initiated in nature by a very small inoculum, perhaps involving in the first instance one or two cells only. If the disease develops, very many more cells are involved, symptoms appear, and the patient dies or recovers.

We can look at that process at two levels: (1) as it involves the individual cell; and (2) as it concerns the susceptible cells of the body as a whole.

1. At the microscopic (cellular) level we have to consider:

(*a*) The entry of virus into the cell.
(*b*) The process of intracellular multiplication.
(*c*) Liberation of virus and cell damage or disintegration.

2. At the macroscopic level we have:

(*d*) The process by which infection spreads from the site of initiation to the other susceptible cells.
(*e*) The process by which infection is overcome.

I shall necessarily have to treat each of these phases in summary and rather dogmatic fashion, but somehow I do not think that I shall leave any of you with the feeling that all is now understood about the pathology of virus infection. I shall be disappointed in fact if here and there I cannot pass over to you some of my own enthusiasm for the idea that in the study of virus action on cells and organisms we have one of the most potent tools for the advancement of fundamental biology. There is an enormous field to be explored within the living cell, and perhaps I could express my own attitude to virus research by saying that we start from clinical medicine—from the patient with influenza, smallpox, or herpes—and pass almost at once to the fundamental biological problems of reproduction, mutation, and survival, in their most generalised form. In the end we shall, I hope, return with ideas and techniques that are directly applicable to human benefit—or at least to the satisfaction of human desires.

Virus Entry into the Cell

To multiply within a cell, the infecting virus particle must pass through the cell surface into the interior. In very many instances this seems to present no difficulty. A wide range of cells, particularly those of mesenchymal origin, have the potential capacity to take small foreign particles into their substances. Many viruses too can multiply within a wide range of cell types including macrophages. At the present time it is reasonable to assume that for those viruses without very marked tissue specificity, and especially for those that are introduced into the body through a traumatised area, no specific mechanism for passage through the cell surface is necessary. Sometimes the trauma required is the bite of a mosquito, as in yellow fever; viruses like herpes simplex and lymphogranuloma venereum probably enter through slight abrasions of mucous surfaces. Such viruses will not be further discussed in this section, but I am by no means certain that a new approach in the future may not show that we are wrong in assuming that no special means exists by which the virus makes contact with and passes through the surface of cells particularly suitable for its multiplication. Biological phenomena have a habit of appearing simple until we find the appropriate tools to investigate them.

INTERACTIONS AT CELL SURFACE

In 1941 Hirst discovered a most effective tool for the study of the interaction of influenza virus and the cell surface, in the form of the hæmagglutination reaction. Many years previously, however, work in which I myself played a part showed that bacterial viruses had also specific relationships with the surfaces of the bacteria they infected, and that methods could be devised for the study of these relationships. From work on these two groups of viruses what is really no more than a probable provisional generalisation can be made—namely, that, when a virus must invade and infect a cell through an intact surface exposed to the environment, a special mechanism for this purpose is usually demonstrable. So far the great bulk of investigation has been done with viruses of the influenza group, including mumps and Newcastle disease of fowls, and in this lecture I shall discuss only this group.

At the Walter and Eliza Hall Institute my colleagues and I have spent most of the last four or five years in work arising out of Hirst's discovery that influenza virus will agglutinate red cells of several species. Similar work has been going on elsewhere, and from the combined effort a fairly clear picture has emerged of the process by which this virus becomes attached to and enters the cells susceptible to its action—i.e., the cells lining the respiratory tract.

---

* University of London lecture given on May 9.

The basic experiments are all due to Hirst (1942). He showed first that agglutination of red cells was associated with adsorption of the virus on to the cell surface. There is adequate evidence that agglutination is simply due to the fact that by adsorption of a virus particle to two adjacent cells a bridge between the two can be formed. When a sufficiency of these bridges form, the cells clump together and are deposited in the characteristic granular masses. Hirst's second finding was that if a mixture of virus and red cells is kept at 37°C with intermittent shaking, and the proportions of the virus free and bound to the cells respectively are estimated at suitable periods, a regular sequence of adsorption and elution is observed. The virus is first very rapidly and almost completely removed from the fluid; then after an hour or two it begins to reappear; and eventually it is present in virtually its original amount. Simultaneously the red cells have ceased to be agglutinated and if they are then collected, washed, and re-tested with fresh virus they are quite inagglutinable. On the other hand the eluted virus is still fully capable of producing the same sequence of effects on fresh cells. The virus in other words displays all the characteristics of enzymic action. For ease of discussion we can describe the sequence as adsorption of virus particles on to receptors of the cell surface, with subsequent destruction of receptors and release of the virus. I should point out that in any actual experiment it is not a matter of one virus particle taking an hour to be liberated from one receptor. The process is one in which there is probably a rapid sequence of successive adsorptions and elutions, adsorption only ceasing to dominate the picture as the number of available receptor sites begins to approach zero.

These experiments were done with red cells, which are not susceptible to infection by influenza virus. Hirst (1943) was again first to show that by using the excised ferret lung an essentially similar process of adsorption and elution takes place. Fazekas de St. Groth (1948a) has studied this process in very great detail, using the more convenient mouse-lung preparation. He has found that, without exception, all the essential phenomena shown by the red-cell surface can be duplicated by the use of the cells lining the respiratory tract.

There is, however, one important difference. In the living animal, virus introduced into the lung via the trachea is absorbed but it is not released. The virus units instead enter the cells, initiating infection.

SOME QUESTIONS

This general reaction between virus and cell surface poses a number of important questions. At the chemical level we would like to know what is the nature of the components responsible for the initial mutual adsorption, and what is the functional nature of the virus enzyme concerned—in other words, what is its substrate, and what is the chemical change induced in the substrate? At the biological level we have the very pertinent question, how can it be shown that this mechanism is in fact involved in the process of infection?

I cannot here describe the experimental and logical processes by which at least partial answers to these questions have been obtained. Some workers would probably consider that the true answers are less definite than those I am going to give. In outline we believe that the receptor substance, which is both the cell component responsible for adsorbing the virus and the substrate of its enzyme, is a mucopolysaccharide probably present in the form of a meshwork on the cell surface and intimately related to lipid and protein components. With slight reservations I consider that the adsorption is mediated through the same groups on the virus surface which function as the enzyme. The enzyme is functionally identical with an enzyme secreted by the cholera vibrio, which we refer to as receptor-destroying enzyme (R.D.E.). This enzyme, which has now been concentrated and partially purified by Ada and French, is a biological reagent of extraordinary interest. Its substrate is present in a wide variety of cell surfaces and tissue extracts and is in particularly high concentration in all human glandular mucins that we have tested. Evidence obtained by Gottschalk and Lind (1949) indicates that a dialysable product results from the action of either influenza virus or R.D.E. on ovomucin. This appears to be an amino-acid-sugar compound that has not yet been fully characterised. I have no doubt that relatively soon the enzyme will be purified and its chemical action fully defined.

The clearest evidence of the importance of these reactions for the process of cell infection can be obtained from Stone's experiments (1948) in which susceptible animals—mouse or chick embryo—were treated with the receptor-destroying enzyme at varying times before infection. In all instances protection to some degree was observed. With some virus strains the protection afforded was very high, with others almost negligible. In the course of these experiments, and in others by Fazekas de St. Groth (1948b), it became clear that cell receptors are constantly being renewed so that no long-lasting protection by this means was ever observed.

This is a very cursory treatment of a topic that could be expanded indefinitely, but I hope it is enough to indicate the general nature of the interaction between virus and cell surface which takes place with influenza virus. Very recently it has been reported that another group of viruses, responsible mainly for encephalitis in animals, will agglutinate mammalian red cells. This will almost certainly lead to an intensive study along somewhat similar lines of the mechanism involved with these neurotropic viruses. There is a rich field for discovery here: if I may be excused for mentioning a completely irresponsible "hunch," I believe the most important thing to be found about poliomyelitis virus is how it enters the nerve-cell.

Nature of Intracellular Multiplication

A virus particle enters a susceptible cell. At the end of a period of the order, usually, of a few hours, the cell has disintegrated partially or almost completely, and a brood of perhaps 50 or 100 fresh virus particles has been set free. In other, apparently similar, cells infection is not followed by multiplication of virus and destruction of the cell. An immense variety of problems arise when we try to determine what happens within the cell between entry of the virus and the liberation of the new generation. The infection of bacteria by phage provides the most suitable experimental material for this problem; but I am here concerned essentially with viruses responsible for human disease, of which the one most convenient for study is influenza virus.

In this field the situation is far less clear than in regard to the surface changes, but much more exciting. Biology, and especially biochemistry, has in recent years been coming much closer to the fundamental problems of replication of organic pattern, of gene-enzyme relationship, and of the provision of building-stones and energy for protein synthesis in the cell. It seems likely that the virus worker may soon be providing an important technical means of assisting in this problem of what takes place within the living cell.

At the present time we are at the stage of exploration and accumulation of rather unrelated experimental data. May I first indicate some of the lines of experimental approach that are available.

The oldest approach is the morphological: there are undant records and pictures available of the histogical changes produced—the various types of inclusion dy and of associated degenerations. In more recent ars the greatly increased interest in the function of cleic acids has been carried over into the virus field, d it has been shown by standard histochemical methods at in the early stages of infection there is with several iruses a great increase in the cytoplasmic concentraon of ribonucleic acid. This is generally interpreted as dicating increased protein synthetic activity in the cell.

Then we have rather ill-defined quantitative data in egard to the disappearance and reappearance of virus bsorbed by susceptible cells in suitable situations. here is no doubt that influenza virus apparently disppears when the cell is entered, in the sense that extracts f the infected cells show much less virus by any available test than would be the case if virus were simply dded to a comparable suspension of ground-up normal ells. Whether this means that the virus particles ctually are converted in the first stage of infection to another form lacking infectivity and the other characteristic features of the virus is a more difficult question. Hoyle (1949) finds that a soluble (smaller-particle) antigen, detectable by complement-fixation, appears before the stage at which the next generation of virus particles is liberated, and he favours the view that this antigen is composed of the smaller units into which the virus breaks down after effective entry into the cell. Much more study is required before this hypothesis can be regarded as established.

INTERFERENCE BETWEEN VIRUSES

A third approach is through the study of interference between viruses. To give a very simple example of this phenomenon I may mention a variant strain of influenza virus "*neuro* W.S.," which unlike any other influenza virus produces fatal encephalitis in mice. If an appropriate amount of this virus (say a 1 : 1000 dilution of a standard brain emulsion) is mixed with normal egg fluid, and injected into mice, all will die in 5 to 7 days with the usual signs of infection of the central nervous system. If, however, the same amount is mixed with egg-fluid virus of a normal influenza virus the mixture will provoke no symptoms. It seems that if one type of influenza virus, which cannot multiply in certain cells, enters them first it renders them incapable of supporting the multiplication of another strain which would normally flourish there. There are many examples of this phenomenon, which has been recently reviewed by Henle (1950). Most workers think that, while under special circumstances this interference may occur at the cell surface, it usually depends on intracellular reactions. Again there are hopes that the analysis of the qualitative and quantitative aspects of interference will lead us deep into the nature of the intracellular environment.

There are a number of puzzling phenomena which may be in some way related to interference and in their turn throw light on intracellular processes. Latent infection is one. How for instance does the herpes virus persist in the deeper epidermal cells of the affected areas of skin between attacks of herpes? Even in the most acute type of experimental infection with a virus like influenza it is most unusual to find every cell showing gross evidence of infection. Some which must have been exposed to infection escape completely. Then there is at least one virus disease of mice in which infection of the young in utero may initiate a lifelong infection in which virus seems to be present in every tissue of the body without producing symptoms or histological changes. All these phenomena show that there is some delicate balance within the cell which determines whether or not an entrant virus will flourish.

MULTIPLICATION OF VIRUSES

The final approach to which I want to refer is one that has been the centre of my own experimental interest during the past year. This is concerned with the production of recombinants from simultaneous infections with two recognisably different strains of virus. It is possible for instance to inoculate mice intracerebrally with a mixture of the neurotropic strain I mentioned earlier, "neuro W.S.," and the serologically distinct non-neurotropic strain MEL, which will give a partial interference effect. By appropriate manipulations virus can be recovered from such a mouse, which, after being proved to be a single type by passage at high dilution, is neurotropic but with the immunological character MEL of the second virus. Enough such experiments have been done to justify a brief consideration of their implications. It seems that in some way the genetic material of two virus particles entering a cell must mingle and then be rearranged. Either the two particles fuse into a zygote, within which some type of rearrangement of genetic units takes place before multiplication begins, or the two particles break down into smaller genetic units which multiply independently to provide a pool from which in the later stages the new generation of virus particles is built up.

Taken as a whole, this evidence in regard to the intracellular multiplication of virus points rather strongly toward the latter alternative. As a working hypothesis applied specifically to the influenza viruses I should suggest that on entering the susceptible cell the virus particle breaks down into a relatively large number—perhaps 200–500—of subunits which are essentially self-reproducing entities. Each is small enough to make some necessary intimate contact with a cellular enzyme system which can provide; for the replication of the virus subunit, the necessary flow of energy and building-stones. As the replication proceeds there is an urgent drain on the protein-synthetic mechanism of the cell, shown first by the increase in ribonucleic acid, and later, as the whole structure begins to break down, by gross morphological changes. From the pool of many thousand subunits present toward the end of the process, there is a reaggregation into the appropriate bundles that make up the infective virus particle.

This hypothesis is quite frankly no more than the speculation which at the moment seems to me to offer the best synthesis of the facts in regard to influenza virus, and the best framework on which to devise further experimental work. If it turns out to be true for influenza virus, I shall be surprised if it is not applicable to most other animal viruses. An essentially similar hypothesis is already current in regard to bacterial virus multiplication (Delbrück and Bailey 1946, Delbrück 1949), and in fact the phage investigations provide one of the strongest reasons for favouring the theory of virus reproduction by simpler subunits.

Spread of Virus Infection in the Body

I have spent so much time on the cellular processes of virus infection that I shall have to pass over the problem of the spread of infection in the body in even more summary fashion. I shall limit my remarks to giving some account of two investigations carried out in my laboratory on the pathogenesis of experimental and natural mousepox (ectromelia) and of experimental influenza in mice. This use of the laboratory mouse as an experimental model of a human disease has its limitations which must never be forgotten. Nevertheless these two investigations, by Fenner on mousepox and by Fazekas de St. Groth on influenza, appear to be remarkably relevant to the understanding of human smallpox and similar exanthematic diseases on the one hand and of the respiratory virus infections on the other.

EVIDENCE FROM MOUSEPOX

Fenner's work has been published in full (1948, 1949). It was concerned primarily with elucidating the processes concerned in the spread of mousepox in groups of mice, and secondarily with a study of the nature of the incubation period between infection and the appearance of the generalised rash. Not only is mousepox serologically similar to variola: a mouse population can be protected against mousepox by vaccination (with vaccinia virus) just as effectively as a human community can be protected against smallpox. In addition it produces an essentially similar skin rash in those mice which do not die acutely, with an incubation period only a little shorter than that of the human disease.

As a result of very extensive and painstaking titrations of the virus content of different organs in the course of infection, Fenner gave the following picture of the pathogenesis of mousepox. The primary infection takes place through some trauma, often minimal, of the skin. Multiplication in the cells at the site of entry gives rise eventually to a macroscopic primary lesion essentially by spread to contiguous cells. Before this stage, however, dissemination via the regional lymphatics and the blood has begun. Most of this virus of the primary viræmia passes to, and infects, cells of the liver and spleen. When multiplication in these organs produces a high virus content, there is a more intense secondary viræmia which is responsible for the initiation of the generalised skin rash. Liberation of the virus into the environment is largely from animals in the stage when the lesions of the rash are breaking down and much infective material is shed. At about the same time, in surviving animals, antibody in the serum is rising rapidly and virus becomes no longer detectable in the internal organs.

If we can generalise from these experiments we can expect to find in any virus disease with a long incubation period the following sequence:

1. A site of primary infection and multiplication.
2. Passage of the virus to those organs best equipped to remove foreign particles from lymph or blood.
3. Multiplication in lymphoid tissue, spleen, or liver, with eventual liberation in much greater concentration into the blood.
4. Symptomatic infection of the skin, general mucous membranes, or other organs.
5. Relatively rapid appearance of antibody, with recovery unless the initial onslaught was too severe.

EVIDENCE FROM INFLUENZA

In the experiments of Fazekas de St. Groth (in the press) with influenza virus the situation was very different. Here the infection in the mice was initiated by administering the virus intranasally, and multiplication of the virus was limited to the cells lining the respiratory tract. There is no direct involvement of anything but the respiratory epithelium of the bronchial tree, including the smallest bronchioles. It is still not quite clear what the connection is between the bronchiolar lesions and the consolidated areas of the lung that are the normal indices of infection used in experimental work on influenza. Any examination of a lung showing minimal lesions, however, will indicate that the process involves areas representing divisions of the bronchioles. An interesting comparison is with a lung infected with a minimal dose of psittacosis virus so as to produce isolated focal lesions. These are quite unrelated to bronchiolar distribution, forming dark spherical lesions which spread centrifugally from the point of initiation.

An influenza virus particle lodges, we may assume, on the surface of a bronchiolar epithelial cell. If it enters the cell the virus multiplies, and, with necrosis of the cell, a second generation of virus particles is liberated on the respiratory surface. Ciliary move will ensure that infection spreads centripetally and centrifugally along the respiratory passages. A simple proof of this can be obtained by inoculating mice with a dose of virus which will produce only one or two small areas of consolidation. On the following day some of the mice are inoculated intranasally with normal saline. This will sweep down into the smaller bronchioles some of any infective virus that may be present in upper levels of the bronchial tree. It will be fou that the mice receiving the second dose of saline will with complete consolidation of the lungs, in contrast the trivial lesions of those receiving one inocula only.

Uncomplicated acute influenza in human beings is essentially a bronchiolitis, as far as can be judged in the absence of direct histological studies on uncomplicated cases. In experimental monkey infections we found (Burnet 1941) that histological damage was rather strictly limited to the bronchioles; the bronchial and tracheal epithelium was apparently normal. What is to be stressed is that infection by viruses of this type is infection over the surface of a sheet of susceptible cells. Passage of virus into lymph-channels undoubtedly occurs, and probably small amounts reach the blood; but in neither case is the virus conveyed to susceptible cells. This surface character of the infection is of great significance in understanding the part played by immunity in influenza.

THE STUDY OF MUMPS

There is one disease, mumps, which may well combine to some extent the characteristics of both the types of infection that I have described. The virus is functionally very similar to the influenza viruses and has essentially the same reactions with the red-cell surface. In all probability there is an initial silent surface infection of influenzal type with entry into the blood-stream. Whether the parotitis results directly from this, or (like the rash in mousepox) results from a secondary viræmia, has yet to be determined. One of the outstanding problems in the pathology of infectious disease is to ascertain the nature of the primary infection in such diseases as measles, smallpox, chickenpox, rubella, and mumps. Only two of these viruses, mumps and variola, can be conveniently handled in the laboratory, and it is from one of these two diseases that we can hope to gain the information.

The Production of Symptoms

Very little work seems to have been done relevant to the means by which symptoms are produced in virus disease. With large doses of influenza virus, as well as of viruses of the psittacosis group and some rickettsiæ, acute toxic effects can be demonstrated in experimental animals. These are not due to any soluble toxin but appear to be referable to some surface activity of the infective particles. It is doubtful whether they have much significance in the actual manifestations of disease. It is probably best at present to look on the intensity of symptoms as essentially a measure of the cell damage that is occurring—the symptom-producing agents being soluble products from the breaking-down cells. The more sudden the liberation of such products the more acute the symptoms. On this view, the sudden onset of symptoms in influenza would be associated with the infection and damage of a large area of bronchiolar epithelium. There is nothing to suggest that it is a manifestation of invasion of the blood-stream by the virus.

Antibody in Virus Disease

For many years there has been a recurrent tendency by the more sceptical of pathologists to decry the rôle of circulating antibody in infectious disease. The fact that phoid bacilli can grow quite actively in the presence of 'antityphoid serum- is apt to over-impress a young thologist. In virus disease we have a rather more ect approach to the significance of antibody than the cteriologists. The normal means of titrating antidy is not in the test-tube but by the direct functional t of seeing whether, when mixed with virus, it will event infection of susceptible cells. If I were teaching munology I should be inclined to start not with ecipitins and agglutinins but with the immune response mumps, influenza, and yellow fever. In these diseases e immediate significance of antibody can be experientally demonstrated; the complications which arise, hen antigen-antibody aggregation reactions in the st-tube are introduced, can be left until later.

CONTRASTS

In yellow fever we have a disease whose whole pidemiology is dominated by the immune response, nd which is due to a virus which can be studied with elative ease. The child born in an endemic region ormally suffers a mild infection, and on recovery remains mmune to yellow fever in most cases *for life.* This mmunity is so regularly associated with measurable ntibody in the blood that all surveys of the extent of ellow fever in Africa or elsewhere are based on such xaminations for antibody.

There is one generalisation in regard to immunity n virus disease which appears to be without exception. Antibody is effective in preventing infection of a cell if it can make contact in adequate concentration with the virus particle before it enters the cell. In yellow fever the conditions for fulfilling this requirement are ideal. The primary infection is associated with a veritable flooding of the blood and tissues with virus, providing an intense stimulus to antibody production. When an immune person is bitten by an infected mosquito the virus must be exposed to maximal antibody concentration in the blood before it can reach the liver or any other suitable nidus for its multiplication.

In influenza we have a very different state of affairs. The virus spreads from cell to cell in the film of liquid bathing the surface of the respiratory epithelium. If our principle is sound, what will determine immunity or not to influenza is the presence of an adequate concentration of antibody, of appropriate serological type, in this surface film. Fazekas de St. Groth has recently completed some beautiful experiments which have established this directly for experimental influenza in the mouse. He has tackled the question with a whole-hearted application of all available techniques, particularly those involving the use of the mouse lung *in vitro.* The experiment I wish to describe was a comparison of the immunity to challenge of two groups of mice both immunised intraperitoneally with an influenza A vaccine. One of them was given in addition an influenza B vaccine intranasally. This second group was far more resistant to challenge with influenza virus A than the one receiving only the homologous vaccine intraperitoneally. Analysis of the levels of A and B antibody in blood and in washings of the respiratory surface of the excised lung, plus a variety of control experiments, showed that the increased immunity was directly correlated with a measurable increase in the available A antibody on the bronchial surface which followed the administration of the heterologous vaccine.

It is difficult to guess what is the actual concentration of antibody in the normal film in terms of that in the blood, but it is almost certainly considerably lower. Immunity against any given epidemic of influenza must be a complex of many factors, even if we forget about the further complication of the dose and degree of dispersion of the infecting dose. The factors will include the titre of circulating antibody and the immunological appropriateness of this antibody to the current serological type of virus, and in addition the relative concentration of antibody in the respiratory film of fluid to that in the blood. This probably varies considerably from one individual to another, and will be modified by minor pathological states of the respiratory tract. Non-specific effects due to the presence and physical state of inhibitory mucoids may also modify the surface conditions in ways which have not yet been assessed.

Finally we may mention herpes simplex; here the virus for the most part remains dormant in certain areas of skin epithelium. It is entirely intracellular and uninfluenced by the large amount of circulating antibody that is always present. When activation by fever occurs, the virus multiplies in a cell which it has not been required to enter. Necrosis and liquefaction, therefore, take place, and give the typical blisters; but, unless the conditions are most exceptional, the virus infection does not extend beyond its initial site. In this circumscription of the lesions we may see one function of the antibody.

It is probably fair to summarise the opinion of most of those concerned with virus disease as a belief that, *in any virus disease in which effective invasion of* susceptible tissues occurs, recovery and subsequent immunity are functions of the production of circulating antibody. The effectiveness of that antibody is determined by the considerations of access to the virus particle before it can enter the susceptible cell that I have just been discussing.

Conclusion

Perhaps I might conclude with a very brief summary of the points I have tried to make.

1. Virus infection is essentially an intracellular process.

2. For some, but not all, viruses there is a rather elaborate mechanism by which the cell membrane is passed.

3. Multiplication of virus within the cell is in all probability a more complex process than binary fission. I am strongly inclined toward the view *that the virus* particle must break down into smaller elements *before* it can make use of the protein synthetic mechanism of the cell for its own replication. And I believe that the further study of this process may throw more light on the protein synthetic mechanism of the cell than any other available experimental attack.

4. The spread of infection is determined (*a*) by the range of cells which are susceptible to virus infection and necrosis, and (*b*) by the anatomical relationship of those cells.

5. Symptoms in virus diseases result from chemical and morphological by-products of the primary cell damage: there is no clear evidence of any toxic products of the virus as such.

6. Recovery and immunity are predominantly determined by the production of antibody. The effectiveness of antibody will depend on the concentration in which it is present at the points where it can block the virus before generalisation occurs.

TREATMENT OF PERNICIOUS ANÆMIA WITH PARENTERAL LIVER EXTRACT

A REVIEW OF FIFTY-ONE PATIENTS BETWEEN 1940 AND 1948

D. L. MOLLIN
M.B. Wales
ASSISTANT LECTURER IN PATHOLOGY (HÆMATOLOGY), POSTGRADUATE MEDICAL SCHOOL OF LONDON

THE amount of anti-pernicious anæmia principle required for initial and maintenance therapy of pernicious anæmia varies from patient to patient. However, many American studies involving large numbers of patients followed for many years suggest that after adequate initial treatment the great majority can be kept in full clinical, neurological, and hæmatological remission on 2 ml. of concentrated liver extract (15 U.S.P. units per ml.) a month (Murphy and Howard 1939, Alt and Young 1940, Evans and Jordan 1941, Strauss et al. 1942, Haden and Bortz 1948).

Wilkinson (1949a and b) has stated that considerably larger doses of liver extract have been required in this country for the adequate treatment of pernicious anæmia than were needed before the war. Further, the dose of liver extract that some workers in this country (Callender and Witts 1949, McSorley 1949) considered advisable for the maintenance treatment of pernicious anæmia appears to be larger than that found necessary by the American workers mentioned above.

These observations have provoked considerable discussion and correspondence (*Lancet* 1949). Impotent extracts and an increase in the amount of anti-pernicious anæmia principle required, perhaps as a result of decreased protein intake, have been suggested as causes.

The object of the work described here was to determine the incidence of relapse in a group of patients with pernicious anæmia treated with parenteral liver extract during 1940–48 and to analyse the causes.

TECHNICAL METHODS

The blood-counts reported in the first part of this paper were done on peripheral blood, and those in the second part on venous blood.

Red-cell counts were done at a dilution of 1 : 200 with Burker or Neubauer counting-chambers. When peripheral blood samples were used, about 500 cells were counted. 3000 cells were counted for the red-cell counts detailed the second part of the paper.

Hæmoglobin was estimated by various modifications of the alkaline-hæmatin and cyanhæmatin methods. Readings were made with a photoelectric colorimeter.

Packed cell volume was measured by Wintrobe's method. The tubes were centrifuged at 3000 r.p.m. for 30 minutes

Effects of Three British Liver Extracts (1940–48)

The red-cell counts of 27 women and 24 men who attended the outpatient department in 1940–48 shown in figs. 1 and 2. The period of follow up individual patients varied from 1 to 11 years. patients were included who had not been recei maintenance injections for at least a year. No new patients were included after the end of 1947. Patients attending in 1940 had been attending for treatment for 1–4 years.

The data are presented as the yearly means of red-cell counts done on each patient. Red-cell counts were usually done at 1–3 month intervals. The total number of observations in a given year is indicated in the upper part of the figure, and the mean of the counts of all the patients attending in that year in the lower part.

The 51 patients were taken from a total of 62 patients attending during this period; 11 patients who did not attend regularly for injection, or who developed serious intercurrent disease during treatment, were excluded.

The patients included in this series came from working-class families. None showed evidence of gross dietary deficiency. Their ages were those of any similar group of patients with pernicious anæmia. Many had the normal complaints of their age; some had arteriosclerosis; others had a raised blood-pressure; and a few had chronic bronchitis. No attempt has been made to assess the importance of these factors.

The patients were treated with three brands of liver extract:

Extract A: a refined liver extract prepared by the Dakin and West process, used during the whole period.

Extract B: an extract described by the manufacturers as "crude," of which 4 ml. was stated to produce an adequate response, and of which the average maintenance dose recommended was 4 ml. monthly; used only after 1944.

Extract C: another brand of refined extract, used only for one patient.

Each batch of these extracts was reported by the manufacturers to have produced a satisfactory hæmatological and clinical response over a period of 14 or 15 days in at least one patient with typical pernicious anæmia in severe relapse, in doses of 2 ml., 4 ml., and 1 ml. respectively. The responses were stated to have been judged by the usual criteria of the reticulocyte response and the subsequent increase in the number of red cells (Minot et al. 1928, Isaacs et al. 1938, Riddle 1940, Della Vida and Dyke 1942).

The initial and maintenance doses of liver extract given to each patient in th present series varied and was determine by the patient's requirements and by th past experience with the extract con cerned. Injections for maintenanc treatment were given in most cases 4-weekly intervals. After 1947 no injec tions were given at intervals of less tha 4 weeks.

RESULTS

From figs. 1 and 2 and table I it wi be seen that there is a tendency for th red-cell count to fall during the perio of observation. This is particularl noticeable after 1946 in the case o both men and women, but the mea

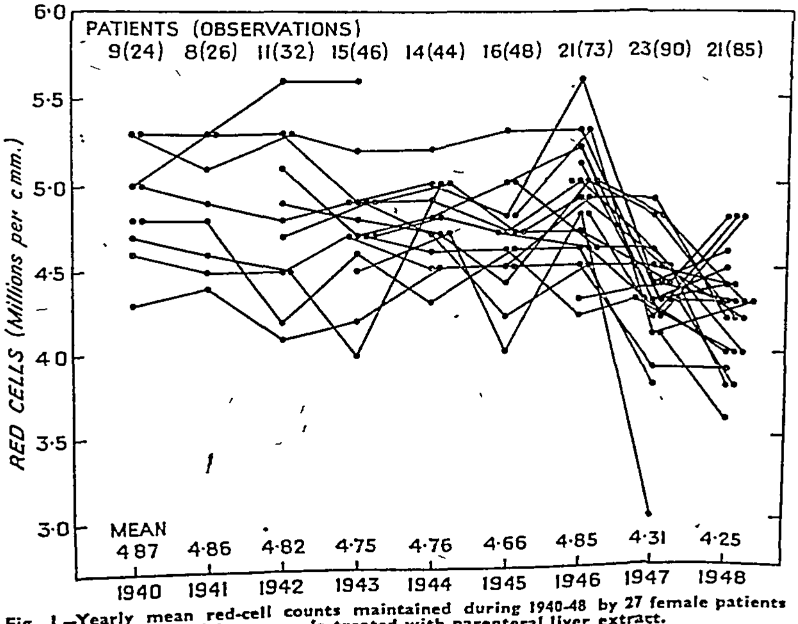

Fig. 1—Yearly mean red-cell counts maintained during 1940–48 by 27 female patients with pernicious anæmia treated with parenteral liver extract.

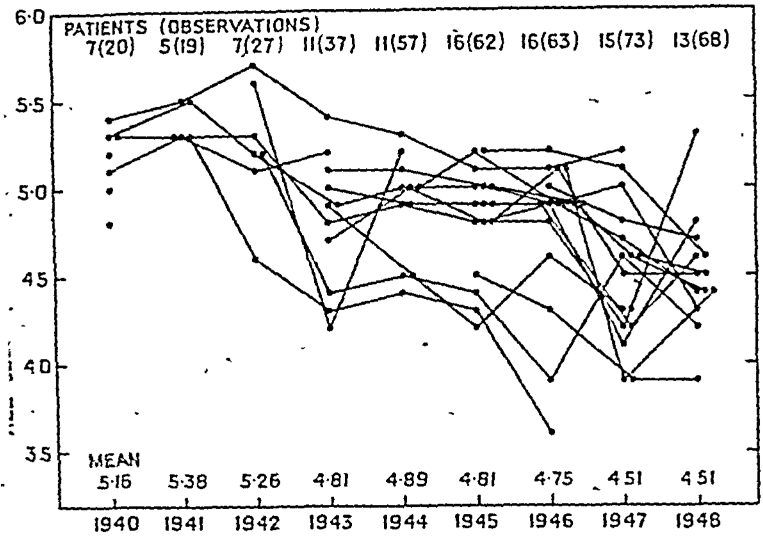

ig. 2—Yearly mean red-cell counts maintained during 1940–48 by 24 male patients with pernicious anæmia treated with parenteral liver extract.

early blood-counts of several patients were unsatisfactory rom 1943 onwards.

In tables II and III are shown the amounts of extract A nd extract B used during this period; the latter was nly used extensively after 1944. From these tables it s evident that the red-cell counts decreased in spite of the use of the same or increased amounts of liver extracts.

In fig. 3 are illustrated the proportion of patients treated with extract A who gave definite evidence of relapse while under this treatment. A patient was considered to be in relapse if there was a decrease in two successive counts of at least 500,000 red cells per c.mm. below the previously maintained level, and/or if clinical symptoms of inadequate treatment developed, such as a persistent loss of well-being and energy, glossitis, paræsthesiæ, or definite signs of subacute combined degeneration of the cord or of peripheral neuritis.

These results confirm that a large number of patients treated with this extract relapsed after 1946. Some patients did, however, relapse from 1943 onwards. It is noteworthy that only 3 out of 29 patients who received a maintenance dose of extract A 4 ml. a month relapsed before the later part of 1946. No record could be found of a patient relapsing on this dose before 1944.

Nine patients were treated with a monthly dose of extract B 4–6 ml. during 1945–46. All remained in excellent remission. During 1947–48 10 out of 12 patients who had received this amount relapsed.

DISCUSSION

Evidence has been presented which indicates that during the period of observation the red-cell counts and clinical condition of patients with pernicious anæmia deteriorated on doses of liver extract previously found adequate for keeping them in remission. The most dramatic decreases in red-cell counts took place after 1946, but there is some evidence which suggests that deterioration started earlier.

These results confirm the widespread impression that larger doses of liver extract than previously used have been recently required to maintain patients in remission. The cause of this must have been that either the extracts were less potent or that there was an increase in the requirements of patients for the anti-pernicious anæmia principle (or principles?).

It is possible that individual requirements for liver extract may increase during the course of pernicious anæmia. It seems unlikely, however, that this has played a significant part in causing the decreases in the blood-counts observed in this series, for the patients have relapsed irrespective of the date of the onset of the disease. Further, several of the patients maintained on 2 ml. or 4 ml. of extract A before 1943 had had pernicious anæmia from the late '20s or early '30s. Nor has such a dramatic increase in requirements been noted in other long-term studies. Most of the patients in this series were old and poor, and their intake of animal protein was not likely to have been much greater in 1936–44 than in the succeeding years. The amounts of vitamin C in their diets may, however, have been less than in their pre-war diets. Most of these patients have received iron and vitamin-C supplements during relapse; in no case was any improvement seen. Therefore, though a dietary deficiency cannot be altogether excluded, a decrease in the potency of the extracts used seems to be by far the most likely cause for the relapses observed. It is realised that extracts of the Dakin and West type have given irregular results in the past (for example, in the cases reported by Wilkinson and Israëls 1947), and relapses in patients on maintenance therapy might be due to the issue of an exceptionally poor batch of extract. However, the cases reported have shown evidence of a consistent decrease in potency between 1947 and 1949.

TABLE II—AMOUNTS OF EXTRACT A USED IN 1940–48

Year	No. of patients treated	No. of patients receiving 2 ml. a month	No. of patients receiving 4 ml. a month	No. of patients receiving 6–8 ml. a month
1940	16	9	6	1
1941	13	7	5	1
1942	18	9	8	1
1943	26	9	15	2
1944	24	7	15	2
1945	23	7	14	2
1946	24	6	14	4
1947	23	3	18	2
1948	17	1	10	6

The evidence presented below supports the view that the relapses observed were due to a decrease in the potency

TABLE I—RED-CELL COUNTS IN 51 PATIENTS WITH PERNICIOUS ANÆMIA ON MAINTENANCE TREATMENT WITH PARENTERAL LIVER EXTRACT IN 1940–48

Year	1940	1941	1942	1943	1944	1945	1946	1947	1948
Mean red-cell count (millions per c.mm.) .. .. Standard error	4·99 ± 0·077	5·06 ± 0·105	4·98 ± 0·112	4·78 ± 0·073	4·82 ± 0·054	4·75 ± 0·018	4·81 ± 0·070	4·38 ± 0·066	4·35 ± 0·061
No. of patients (men and women)	16	13	18	26	25	32	37	38	34

The difference between the mean red-cell counts of 1946 and 1947 would occur by chance less than 1 time in 1000 (P = < 0·001). As regards the mean red-cell counts in the remaining years there is no real difference between the values in any two successive years. However, if all the values for 1940, 1941, and 1942 are compared with those for 1943, 1944, and 1945, there is a difference which again would only occur by chance once in 1000 times (P = < 0·001).

TABLE III—AMOUNTS OF EXTRACT B USED IN 1945–48

Year	No. of patients treated	No. of patients receiving 4 ml. a month	No. of patients receiving 6 ml. a month	No. of patients receiving 8–12 ml. a month
1945*	9	4	0	5
1946	13	7	2	4
1947	14	8	3	3
1948	16	7	5	4

* One patient in this group started maintenance treatment in 1944.

of liver extracts and not to an increase in patients' requirements for anti-pernicious-anæmia principle.

Effect of American Concentrated and Refined Extract

Two batches of an extract made by Lederle Laboratories and sold under the name of 'Concentrated Solution Liver Extract Parenteral' (15 U.S.P. injectable units per ml.) were given to 25 unselected patients attending Hammersmith Hospital for maintenance injections of liver extract. 19 patients were from the series already described above. The other 6 patients started their treatment after 1947 and were not included above for this reason. In most cases Lederle's extract was administered in doses anticipated to be equivalent to those of the liver extracts used previously. It was considered that, if a given dose of extract was reputed to be capable of satisfying the clinical test of potency commonly used in this country, the potency of that dose should be roughly equivalent to 15 U.S.P. injectable units. This method of comparison is admittedly crude, but it is perhaps better than a comparison based on volume alone.

Injections had previously been given at monthly intervals in all but 2 cases. The same intervals were used for the new extract, which was given in each case for four months. Blood-counts were done at 2–4 week intervals for at least 3 months before the change of treatment, and were continued at similar int during the period of treatment with Lederle's extract. Vitamin C 100–200 mg. daily and ferrous sulphate gr. 9–12 daily were given for at least three months before the change of treatment. Patients were not informed of a change to a new extract, and direct questioning was avoided.

The extract was also given to 3 patients in moderately severe relapse who had neglected treatment for 3–9 months (cases 26, 27, and 28). Case 26, when first admitted, responded only very slightly to two separate injections of as much as 8 ml. of two different batches of extract C. She had, in consequence, been considered to be a possible case of refractory megaloblastic anæmia and had been treated with folic acid, to which she responded well. Case 27 had not maintained a red-cell count above 3,800,000 per c.mm. on extract C 2 ml. a fortnight. Case 28 had responded moderately well to extract B 8 ml weekly. These three patients were given 2 ml. (30 U.S.P. units) of Lederle's extract at fortnightly intervals. These injections were continued for four months.

RESULTS

Of the 28 patients treated with Lederle's extract 23 showed either a clinical or a hæmatological response or both. Of the 25 who had been previously receiving regular maintenance injections of other liver extracts 20 responded. All 3 patients (cases 26, 27, and 28) who had neglected treatment responded far more satisfactorily to the new extract than they had to the extracts previously used.

Details of their responses are given in table IV and in figs. 4 and 5. The initial red-cell counts of each patient are the mean of the counts of the two months before treatment was changed. The final recorded red-cell counts are the mean of the counts of the third and fourth months after the new injections were started. Three or four months were allowed to elapse so that the

l-cell counts might become steady at new levels. ere was naturally evidence of improvement before this those patients who responded to treatment.

In fig. 4 are recorded the changes in red-cell counts; nost without exception there were a significant crease in the count and an accompanying decrease in ean corpuscular volume (fig. 5). The mean red-cell unts of the men and women increased to within limits at compare well with those of other patients treated ith Lederle's extract and on whom blood-counts were ade on venous blood * (Evans and Jordan 1941, Strauss al. 1942).

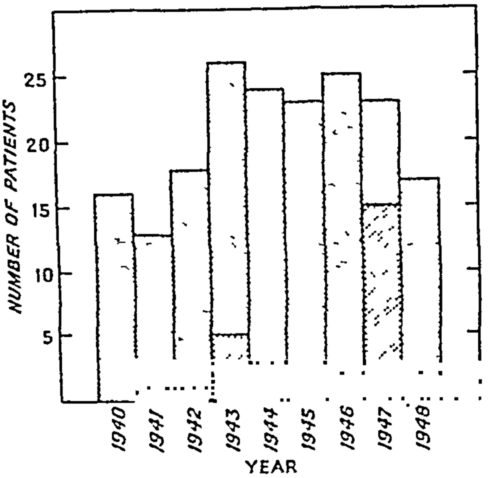

Fig. 3—Incidence of relapse of pernicious anæmia in patients receiving regular injections of extract A: each column indicates number of patients attending for treatment; hatched area of each column indicates number of patients who relapsed.

The clinical improvement in all those who responded was as striking as the hæmatological improvement. Many patients said they were better than they had been for years. There was improvement in well-being and appetite and increase in energy and spirit. Glossitis or paræsthesiæ if present disappeared, as well as the common feeling of "needing an injection" towards the end of the month.

The red-cell counts and blood picture of two patients treated with a monthly injection of Lederle's extract 1 ml. became normal within three months.

In 15 out of 19 patients treated with 2 ml. a month there was a definite response to the change of treatment. The blood-count and mean corpuscular volume in 13 of these patients became normal. Cases 10, 22, and 24 improved considerably but would probably have benefited from larger doses. Only in 4 patients in this group (cases 14, 16, 21, and 23) was there no definite change in either clinical or hæmatological state; in 1 patient the blood picture was normal before treatment; and in 3 there was a mild macrocytosis which persisted in spite in the change of treatment.† These patients were in good clinical remission before the change in treatment.

Four patients were treated with a monthly dose of 3 or 4 ml. of Lederle's extract. 3 responded well; their blood-counts and mean corpuscular volume became normal. In 1 patient no significant change was detected; slight macrocytosis persisted (case 25).

The blood-counts of the 3 patients who had neglected treatment were well within normal limits by the third month after treatment with Lederle's extract had been initiated. A mild macrocytosis persisted, however, and possibly the doses they received were still suboptimal.

Discussion

In the first part of this paper evidence was presented which indicated that the blood-counts of patients with pernicious anæmia who attended Hammersmith Hospital for maintenance injections of liver extract were definitely lower from 1946 onwards than they had been previously. This fall had taken place despite the fact that these patients had received the same, or even larger, doses of liver extract. It was suggested that the probable cause of this was that the liver extracts were less potent than formerly.

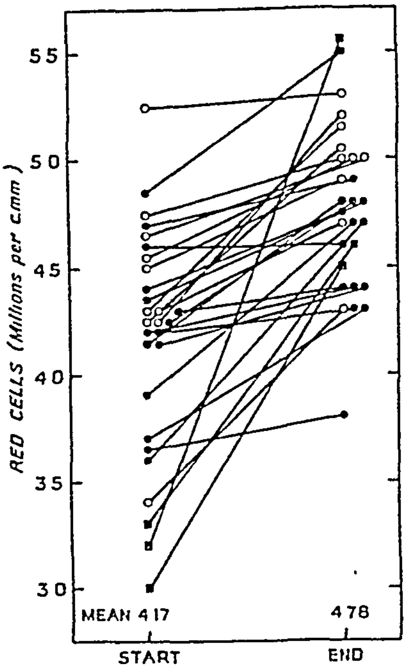

Fig. 4—Effect of treatment with Lederle's concentrated liver extract (15 U.S.P. units per ml.) on red-cell counts of 28 patients with pernicious anæmia, 25 of whom had previously been receiving regular injections of other extracts: black and open circles, *red-cell counts of the 25 patients*; black circles, red-cell counts of females; open circles, red-cell counts of males; black squares, red-cell counts of 3 patients who had neglected treatment for 3-9 months.

In the second part of this paper, evidence is presented which supports this view. In 23 of 28 patients treated with Lederle's liver extract there was a definite and often dramatic improvement. This response followed the use, in most cases, of doses considered to be equivalent to those of the brands previously used, equivalence being judged on the basis of the reputed potency of the extracts as revealed by clinical trial. The two batches of Lederle's extract were therefore significantly more potent.

The work described in part 2 does not necessarily indicate what would be the maintenance requirements in this country of patients treated with such an extract. The results are those of the treatment of patients in mild or moderately severe relapse. They do, however, suggest that the probable requirements of these patients, if

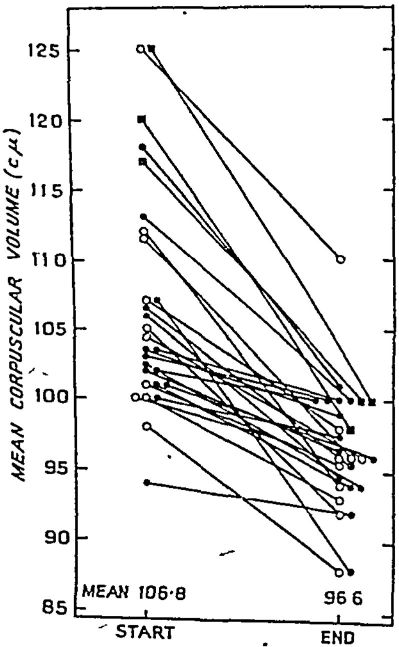

Fig. 5—Effect of treatment with Lederle's concentrated liver extract (15 U.S.P. units per ml.) on mean cell volume of the same patients as in fig. 4.

---

* Red-cell counts made on venous blood are reported to be 5% lower than those made on peripheral blood (Strauss and Burchenal 1942).

† It is not known if still larger amounts of liver extract would have abolished this macrocytosis. In 1 patient at least, doses of 80–100 μg. of vitamin B_{12} a month did not alter the blood picture.

maintained with this extract, would not be significantly greater than those found desirable in America—i.e., 1 or 2 ml. (15–30 U.S.P. units) a month, 2 ml. (30 U.S.P.) a month being the optimal dose for most patients (Haden and Bortz 1948).

On the basis of the results reported here it is felt that the use of relatively impotent liver extracts was the main reason why patients in this country had required such large doses for adequate treatment.

Two batches of the concentrated liver extract produced by Lederle Laboratories were used in this work. It is not known if this high potency is characteristic of all batches of this extract. It has been demonstrated by microbiological assay that the amount of vitamin B_{12} in the various brands of liver extract available in this country and in America varies considerably (Rickes et al. 1948, Cuthbertson et al. 1949, Shaw 1949a). It is probable also that the potency of batches produced by the same process may vary. Nevertheless it is noteworthy that, for two years before Lederle's extract was used, no batches of comparable potency were found among any of the British extracts used in this series, except some samples of extract B produced in 1944, and kindly supplied by Dr. J. Mills. Many more of the patients subsequently treated successfully with Lederle's extract had been treated for periods up to a year or more with many different batches of other extracts without significant alteration in their condition.

At first sight it is difficult to reconcile the relative therapeutic impotency of extracts with the manufacturers' claim that all batches of liver extract are submitted to clinical trial before issue. Though it has been suggested that not all batches of liver extracts are subjected to clinical trial (Wilkinson 1949a), most reputable manufacturers have apparently been at pains to obtain clinical trials on their products (Shaw 1949b, Smith and Cuthbertson 1949). Further, Callender and Witts (1949) have noted a similar relative impotency at high red-cell counts with extracts they have themselves clinically tested.

The unsatisfactory nature of the clinical test as a method of accurate quantitative assay is well known and has been recently emphasised by Shaw (1949b). It is felt, however, that the wide variation found in practice between the potency of extracts said to have passed satisfactorily the clinical test, and the fact that extracts which give satisfactory clinical tests when given to patients with low red-cell counts are relatively impotent in similar doses at higher red-cell counts for maintenance, indicate that the clinical test is not only a poor method of assay of the relative potency of extracts but also an unsatisfactory guide to the requirements of a patient for anti-pernicious anæmia, whatever the red-cell count.

These discrepancies can be explained by the following considerations. It is becoming clear that extracts of widely different content of anti-pernicious anæmia factor produce only relatively small differences in hæmatological effect when given to patients with pernicious anæmia in *severe* relapse. So-called satisfactory responses may be observed with low red-cell counts, without the complete requirements of the patients being satisfied. This, coupled with the fact that different patients differ in their responses to the same dosage of anti-pernicious anæmia factor, probably explains how "satisfactory" clinical trials may be obtained when extracts of inferior therapeutic potency are administered to patients in severe relapse—a state in which they are usually deemed particularly suitable for trial purposes. These considerations also probably explain the apparent anomaly that a patient's requirements for the anti-pernicious anæmia principle may seem to be greater with a high red-cell count than with a low one.

When the work described here was nearly finished, microbiological assay of the vitamin-B_{12} content of liver extracts became possible. One of the batches Lederle's extract has been assayed; it con 22–25 µg. per ml.‡ Where it has been possible to batches of British extracts used in this hospital, t vitamin-B_{12} content has been found to be much sm It is too early to be certain whether the vitamin-B group of substances is the only therapeutically ac material in liver extract or whether any parti method of microbiological assay measures all the "vita-min B_{12}" present. The assay results, however, in instance support and parallel the clinical findings.

It should be emphasised that all American ext are not considered to be necessarily more potent those obtainable in this country. The information avail suggests that considerable variation exists in Ameri too (Rickes et al. 1948, Haden and Bortz 1948). Furth it is to be hoped that the combined use of clinical tri and microbiological assay of the vitamin-B_{12} content of liver extracts will lead to a higher and more constan level of potency in liver extracts and solve some of the difficulties that have beset both clinicians and manufacturers.

Summary

The clinical and hæmatological condition of 51 patients with pernicious anæmia who received maintenance treatment with parenteral liver extracts during 1940–4 is reviewed. The red-cell counts and clinical condition of the patients deteriorated during this period. Deterioration was greatest from the end of 1946 onwards, but in some patients it began earlier.

Twenty-eight patients previously treated with other liver extracts were given injections of two batches of concentrated refined liver extract (15 U.S.P. units per ml. prepared by Lederle Laboratories. The red-cell cou and clinical condition of most of these patients strikingly improved. The new extract was given in doses judged to be equivalent to the doses of the liver extract previously used.

It is suggested that the use of relatively impotent liver extracts was the main reason why the condition of the patients deteriorated between 1940 and 1948.

An explanation is suggested for the anomaly of obtaining an apparently satisfactory clinical trial with liver extracts of unsatisfactory therapeutic potency.

I wish to thank Dr. J. V. Dacie for his advice and encouragement throughout this investigation; the physicians of the Postgraduate Medical School for permission to treat their patients; the Lederle Laboratories Division of the American Cyanamid Company for supplying the liver extract used and Mr. J. Linehan and Mr. L. Wallett for technical help.

TREATMENT OF SYPHILIS DURING PREGNANCY

W. V. Macfarlane
M.D. Edin., D.P.H.
MEDICAL DIRECTOR, VENEREAL DISEASES DEPARTMENT, NEWCASTLE GENERAL HOSPITAL, NEWCASTLE UPON TYNE

In treating syphilis during pregnancy, we have two bjects: (1) to protect the unborn child, and (2) to cure he expectant mother, who may soon become pregnant gain. This paper records the results of treating 300 regnant women with penicillin in conjunction with rsenic and bismuth.

MORBIDITY AND MORTALITY OF INHERITED SYPHILIS

Kampmeier (1946) found that, when syphilis goes untreated, pregnancy terminates in miscarriage or stillbirth in 24% of cases; in 20% the offspring are born healthy and in 56% they are born with syphilitic infection. Of the infected infants one in four will die in the first month and some of the other three may develop late manifestations. Women with untreated syphilis are said to have a stillbirth-rate 8 times higher than that of non-syphilitic women, and the mortality-rate of their infants in the first week of life is 3 times the normal. Inherited syphilis makes the child more prone to intercurrent infections, and generally speaking, of all the children born to untreated syphilitic women, 40% die before attaining the age of one year. The incidence of premature births is no higher for syphilitic pregnant women than for others.

FIELD OF INVESTIGATION

The 300 patients were drawn from rural, urban, heavy industrial, and seaport areas in the counties of Northumberland and Durham and the cities of Newcastle upon Tyne and Gateshead.

As the local incidence of contagious syphilis in females of childbearing age increased tenfold during the war years, routine Wassermann blood-tests for women attending antenatal clinics were introduced in 1943. Between 1944 and 1949, 71,645 such tests were performed and 515 (0·7%) women with a "positive blood" were referred to our department for further examination. Of 398 who attended, 62 were found to be free from syphilis, 36 were receiving treatment elsewhere, another 60 had already received an adequate amount of arsenic and bismuth, 35 were chronic defaulters, and the remaining 205 were infected and untreated.

The incidence of positive Wassermanns (0·7%) is perhaps slightly lower than that for other areas in Great Britain; 1%, the established figure for Norway, is probably nearer the actual figure for this country. According to Kampmeier (1946), Beck and Daily maintain that about 10% of syphilitic pregnant women give a negative Wassermann, and it is therefore possible that more than 0·7% of the women tested were in fact infected.

To these 205 pregnant women thus found to be syphilitic and hitherto untreated, I have added another 95 patients who reached the clinic through other channels. Of the total 300, 132 (44%) suffered from primary or secondary syphilis, 122 (41%) had no symptoms at all, 7 (2%) showed evidence of late infections (e.g., tabes dorsalis or tertiary lesions), and 39 (13%) had congenital syphilis. Latent infection was treated as energetically as contagious syphilis; for the infected female who is no longer contagious can still transmit the disease to the fœtus as long as twenty years after acquiring the infection. Those suffering from inherited syphilis were given treatment rather for their own benefit than to safeguard the fœtus. Beerman et al. (1942), reviewing recent literature, concluded that "third generation syphilis, if it exists, must be uncommon since most of the reported cases fall down when subjected to critical analysis and the strict criteria of Fournier and Finger."

TREATMENT SCHEDULE

Arsenic ('Novarsenobillon' or 'Stabilarsan') was administered intravenously: the initial dose of 0·3 g. was repeated after ninety-six hours; thereafter 0·45 g. was given for nine weeks at intervals of seven days. At the same time 0·2 g. of bismuth oxychloride was given by deep intramuscular injection once weekly for thirteen weeks. Altogether, the thirteen-week schedule included 2·6 g. of bismuth and 4·65 g. of arsenic.

A course of penicillin was given before (in the majority of cases), during, or after the completion of, the arseno-bismuth part of the treatment. Irrespective of the frequency of administration and the type of preparation employed, a total of 2·4–3 mega-units was given to patients with seronegative primary syphilis and a dose of 4 mega-units to all the others. In deciding the initial dosage of penicillin we took account at first of the possibility of actual or threatened abortion; but experience showed this precaution to be unwarranted. For those patients (the majority) who were admitted to hospital, the original three-hourly aqueous-injection schedule was soon replaced by 0·3 mega-unit of oil-wax injections given twice daily for five to seven days according to the type of infection. Domestic difficulties and bed shortage, especially the former, precluded a longer sojourn in hospital, but it was an advantage to admit the patient for a few days (1) because it ensured that she received her full quota of penicillin, (2) because it won her future coöperation, (3) because it provided a rest, welcomed and appreciated by many harassed housewives, and (4) because it solved the problem of attendance at the clinic, which distance and lack of transport often made difficult. Of 20 women who were permitted to attend as outpatients for once-daily oil-wax injections—over a period of eight to fourteen days, according to the type of syphilis—2 had to come into hospital to complete their treatment and 3 failed to bring their infants for examination.

The above penicillin-arseno-bismuth schedule, known as a P.A.B. unit, was at first regarded as adequate for contagious and latent syphilis in expectant mothers. However, when 600 patients (409 males and 191 females) suffering from seropositive contagious syphilis were treated in this clinic with one P.A.B. unit, the number of relapses was 16 (2·67%) of which 3 were clinical and 13 were serological. (The observation period ranged from six months in all to forty-two months for 34 patients.) Though this relapse incidence was small, we thought that better results would be obtained by giving 2 P.A.B. units or more, and from July, 1948, onwards this became our custom. It is still too early to say whether the results are better.

Since a P.A.B. unit required thirteen weeks to complete, those reporting late in pregnancy could only receive a full course of penicillin, plus a varying fraction of heavy metal, before delivery. Of the 300 women in our series, 33 (11%) failed to complete their course of arsenic and bismuth, since they reported no earlier than the third trimester of pregnancy. This lateness was attributable to the fact that some rural antenatal clinics are only held monthly, and to the belief of some women that there is no need to go to the clinic before the sixth month. But lateness in starting treatment did not seem to make much difference to the effects on the child, and the course was concluded after recovery from the confinement. Likewise, satisfactory results seemed to be obtained irrespective of the virulence or type of maternal infection (table I).

RESULTS

Table I shows the results of pregnancy in the 300 women who before delivery received a full course of

TABLE I—OUTCOME OF PREGNANCY IN 300 WOMEN WHO RECEIVED AT LEAST 1 P. + ¼ A.B.

* 3 infants born full-term alive and apparently well but the mothers refuse to have them tested. 11 mothers left the district.

penicillin plus at least a quarter of the course of arsenic and bismuth (1 P. + ¼ A.B.). It will be seen that satisfactory results were obtained irrespective of the virulence or type of maternal infection.

Of the abortions, 1 was self-induced, 2 were probably not syphilitic in origin since they occurred before the sixteenth week of pregnancy, and no apparent cause could be found for the remaining 2. Of the deaths in the first month, 3 were attributable to convulsions and a 4th to pneumonia, which also accounted for the death of another under twelve months. Unfortunately, since none of these 4 children were in hospital when they died, necropsies were not performed. Of the 10 stillborn children 1 was examined post mortem, with negative findings; but the part played by syphilis in the other 9 is difficult to assess.

When the outcome of pregnancy in these women under treatment is compared with the outcome of their previous pregnancies (table II) it is clear that treatment protects the fœtus. Excluding an adverse stillbirth-rate, the figures bear comparison with those of the city of Newcastle upon Tyne during the same period. No doubt, however, the figures for the city, being so much larger, are less liable to statistical error.

MANIFESTATIONS OF INTOLERANCE OF TREATMENT

Apart from local discomfort and stiffness—noticeable especially amongst those receiving the original three-hourly aqueous injections of impure calcium penicillin salt, which also often produced low-grade fever—penicillin produced no untoward results. Arsenic and bismuth were very well tolerated save in 2 patients who developed on their limbs localised patches of erythema accompanied by itching and irritation, which readily responded to dimercaprol (BAL) administered twice daily for two days and three days respectively. Each treatment with dimercaprol consisted in deep intramuscular administration of the contents of one ampoule (2 ml. of a 5% solution) as supplied at that time by the Medical Research Council. In our experience the use of dimercaprol has almost always arrested arsenical dermatitis when given in the early stages, and has thereby considerably reduced the dangers attendant on neoarsphenamine treatment.

COMMENTS ON TREATMENT

Antisyphilitic treatment given in pregnancy should attempt not only to safeguard the fœtus but also to cure the mother. It should occupy the least possible time and preferably should be completed during pregnancy. Does penicillin meet all these requirements? Its main advantage is that it enables the treatment schedule to be shortened: in pre-penicillin days arsenic and bismuth treatment, to give optimum results, had to be started by the fifth month of pregnancy at the latest. With modern products, penicillin very rarely produces signs of intolerance, or pain and discomfort.

As to protection of the fœtus, Goodwin and Moore (1946), Ingraham et al. (1947), and a host of other authors report excellent results from its employment, by itself, during pregnancy. The frequency of administration and the total dosage remain to be determined, and the original scheme by which 2·4 mega-units was given at intervals of two to three hours over seven and a half days can produce adverse results (Cole et al. 1946) Speiser et al. (1947) advocate at least 4 mega-units, while Ingraham et al. (1947) report an unfavourable pregnancy outcome in 5% of women with symptoms of early syphilis and in 1·6% of those with early latent infection, irrespective of the type of penicillin course used. The Council of Pharmacy and Chemistry (1948) state that satisfactory results attend the administration of 4–6 mega-units, given in divided doses every two to three hours for eight to fifteen days. But such frequent treatment must be a strain on staff and patient alike, and few expectant mothers in our part of this country can afford to stay in hospital longer than a week. Also the question arises whether such treatment will prove equally effective in exterminating the maternal disease, especially the early contagious stage.

Moore (1948) estimates that relapse occurred in 25–35% of those suffering from contagious syphilis who had been given 2·4 mega-units in three-hourly doses over seven and a half days. More recently (1949), advocating 10 injections of 0·6 mega-unit of procaine penicillin in aluminium monostearate, given daily or less frequently, he estimates that in early contagious syphilis a 10–15% relapse-rate may be anticipated. While appreciating that the patient need not be in hospital for the latter form of treatment, the relapse-rate is still high. Administration of aqueous penicillin three-hourly, or of procaine aluminium stearate penicillin daily, is designed to maintain an adequate blood-penicillin level; but it is by no means the unanimous opinion that penicillin treatment should be planned with this end in view.

With all due admiration for such enterprise, I prefer more conservative therapy and still adhere to the suggestions made in 1945 by Colonel L. W. Harrison (then chief adviser in venereology to the Ministry of Health) concerning the combined use of penicillin and heavy metals. Much has been written about the toxicity of arsenic and bismuth in pregnancy, but is it really so formidable? In the present series the very few who manifested intolerance responded remarkably well to the early administration of dimercaprol. This valuable drug has proved very successful when administered in

TABLE II—OUTCOME OF PREGNANCY IN INFECTED AND HEALTHY WOMEN

the outpatient department to all showing early signs and symptoms of intolerance to heavy-metal treatment.

It may be suggested that penicillin alone should be given during pregnancy, to protect the fœtus, and the arseno-bismuth part of the treatment should be deferred until pregnancy is over. A careful analysis of the problem of default in this department has provided overwhelming evidence against such a procedure, since a large proportion of pregnant women with latent infection fail to appreciate the gravity of the disease and default after confinement.

DIAGNOSIS OF INFANTILE INHERITED SYPHILIS

Except in virulent infection, signs of inherited syphilis are seldom well developed before the third week of life. A thorough clinical examination—especially of the skin, mucosal surfaces, abdominal viscera, and skeletal system—may fail to reveal any abnormality; nutrition may be normal or nearly so; yet the mother's history of inadequate treatment in pregnancy should warn the clinician that the infant may be infected. In such cases radiological investigation of the long bones shortly after birth may reveal widespread epiphyseal or periosteal abnormalities. Where serological findings in early infancy are giving cause for anxiety, radiological examination must be repeated even if the initial findings were negative. Further examination is similarly called for where there are radiological abnormalities but the serum test is negative. Intensive bismuth therapy during the last few weeks of pregnancy may cause increased density in the metaphyseal regions during the first six weeks of life, but repeated X-ray examination during the ensuing weeks will reveal a reduction in the density. If they become apparent later than the sixth or eighth week of life, bone abnormalities may be due to other conditions, such as rickets, familial hæmolytic anæmia, or erythroblastosis.

That the diagnosis may rest on serological examination alone is shown by a review of 58 consecutive cases of inherited syphilis in children under five years of age reporting at this clinic: of 39 under one year of age 12 (31%) showed no clinical evidence of the disease, and 7 of the other 19 were likewise clinically negative. In the absence of clinical or radiological evidence, however, an initial positive result with the Wassermann test (which is the one employed in this clinic) is possibly of no real significance. It may merely indicate the transfer of syphilitic reagin from the maternal to the fœtal circulation, in which case (*a*) the degree of positivity will not exceed that of the mother and (*b*) the result will become negative by the fourth month at latest. The infant which preserves its initial high titre or maintains a high fluctuating level beyond the early weeks of life, should be regarded as infected. Occasionally an infected infant appears healthy, has a negative *initial* blood test, but shows a steadily rising titre in the first few months of life.

SUMMARY

In 300 pregnant women, syphilis was treated with penicillin and also arsenic and bismuth. All the women received their scheduled dosage of penicillin (2·4 to 4·0 mega-units) and at least a quarter of their scheduled dosage of arsenic (4·65 g.) and bismuth (2·6 g.) before delivery, but in 33 cases the course of arsenic and bismuth had to be completed after the child was born.

As regards the outcome of pregnancy, the results were very satisfactory, even when the disease was virulent and treatment was begun late.

Penicillin with small amounts of arsenic and bismuth will protect the fœtus; but it may not fully cure the mother. A conservative form of treatment is therefore advisable, and it is suggested that all syphilitic pregnant women should have a full course of arsenic and bismuth as well as penicillin. Such treatment is well tolerated.

In the first few weeks of life a positive Wassermann reaction, in an apparently healthy infant, does not necessarily imply that infection has been inherited, and a negative reaction does not necessarily imply that infection has *not* been inherited. Repeated serological examination is necessary before reaching a conclusion.

EXCRETION OF INTRAVENOUSLY ADMINISTERED DEXTRAN *

LARS ENGSTRAND
M.D. Stockholm

BERTIL ÅBERG
Med. Kand.

From the Departments of Experimental Surgery and of Clinical Biochemistry, Karolinska Sjukhuset, Stockholm

PARTLY hydrolysed dextran was introduced as a plasma substitute by Grönwall and Ingelman (1944, 1945). These and other investigators, such as Thorsén (1947, 1949), have expressed the opinion that in vivo dextran is oxidised and broken down. Ingelman (1949) found that in rabbits given thyroid extract intravenously administered dextran disappeared from the blood more rapidly than usual; and he suggested that the increased metabolism accelerated the breakdown of dextran.

Several groups of workers, including Grönwall and Ingelman (1944, 1945), Bohmansson et al. (1946), and Bull et al. (1949), have reported that 20–30% of the injected dextran is excreted by the kidneys during the first 24 hours. Bull et al. (1949) concluded that the fate of the remaining 75% was still in doubt. By chemical quantitative and serological non-quantitative methods, they found that a small amount of dextran was retained in the body tissues, the lymph-nodes and spleen having the highest content. Even 56 days after administration, dextran could be detected serologically in the tissues. Certainly a small amount of dextran is normally taken up by the reticulo-endothelial system.

Bull et al. (1949) found no sign of enzymatic breakdown of dextran when it was incubated with blood, tissue extracts, and tissue suspensions. Indeed, taking into account the specificity of the diastatic enzymes of the body, enzymatic breakdown of dextran seems improbable; and this substance is probably eliminated in some other, unknown, way.

The high permeability of the liver sinusoids and of the capillaries of the intestinal wall led us to investigate the possible elimination of dextran from the blood in these organs.

EXPERIMENTAL RESULTS

For the analyses of dextran two methods of estimation were used:

1. Treatment of the media with glacial acetic acid and basic lead acetate. After filtration, the dextran content was determined polarimetrically, + 190° being taken as the specific rotation of dextran. Proteins were removed by boiling with Sörensen reagent.

2. The method described by Hint and Thorsén (1947) for estimating dextran in blood.

Uptake by liver and intestine.—Rabbits narcotised with 'Dial' were given dextran intravenously. Blood

* 3 infants born full-term alive and apparently well but the mothers refuse to have them tested. 11 mothers left the district.

penicillin plus at least a quarter of the course of arsenic and bismuth (1 P. + $^1/_4$ A.B.). It will be seen that satisfactory results were obtained irrespective of the virulence or type of maternal infection.

Of the abortions, 1 was self-induced, 2 were probably not syphilitic in origin since they occurred before the sixteenth week of pregnancy, and no apparent cause could be found for the remaining 2. Of the deaths in the first month, 3 were attributable to convulsions and a 4th to pneumonia, which also accounted for the death of another under twelve months. Unfortunately, since none of these 4 children were in hospital when they died, necropsies were not performed. Of the 10 stillborn children 1 was examined post mortem, with negative findings; but the part played by syphilis in the other 9 is difficult to assess.

When the outcome of pregnancy in these women under treatment is compared with the outcome of their previous pregnancies (table II) it is clear that treatment protects the fœtus. Excluding an adverse stillbirth-rate, the figures bear comparison with those of the city of Newcastle upon Tyne during the same period. No doubt, however, the figures for the city, being so much larger, are less liable to statistical error.

MANIFESTATIONS OF INTOLERANCE OF TREATMENT

Apart from local discomfort and stiffness—noticeable especially amongst those receiving the original three-hourly aqueous injections of impure calcium penicillin salt, which also often produced low-grade fever—penicillin produced no untoward results. *Arsenic and* bismuth were very well tolerated save in 2 patients who developed on their limbs localised patches of erythema accompanied by itching and irritation, which readily responded to dimercaprol (BAL) administered twice daily for two days and three days respectively. Each treatment with dimercaprol consisted in deep intramuscular administration of the contents of one ampoule (2 ml. of a 5% solution) as supplied at that time by the Medical Research Council. In our experience the use of dimercaprol has almost always arrested arsenical dermatitis when given in the early stages, and has thereby considerably reduced the dangers attendant on neoarsphenamine treatment.

COMMENTS ON TREATMENT

Antisyphilitic treatment given in pregnancy should attempt not only to safeguard the fœtus but also to cure the mother. *It should occupy the least possible time and* preferably should be completed during pregnancy. Does penicillin meet all these requirements? Its main advantage is that it enables the treatment schedule to be shortened: in pre-penicillin days arsenic and bismuth treatment, to give optimum results, had to be started by the fifth month of pregnancy at the latest. With modern products, penicillin very rarely produces signs of intolerance, or pain and discomfort.

As to protection of the fœtus, Goodwin and Moore (1946), Ingraham et al. (1947), and a host of other authors report excellent results from its employment, by itself, during pregnancy. The frequency of administration and the total dosage remain to be determined, and the original scheme by which 2·4 mega-units was given at intervals of two to three hours over seven and a half days can produce adverse results (Cole et al. 1946). Speiser et al. (1947) advocate at least 4 mega-units, while Ingraham et al. (1947) report an unfavourable pregnancy outcome in 5% of women with symptoms of early syphilis and in 1·6% of those with early latent infection, irrespective of the type of penicillin course used. The Council of Pharmacy and Chemistry (1948) state that satisfactory results attend the administration of 4–6 mega-units, given in divided doses every two to three hours for eight to fifteen days. But such frequent treatment must be a strain on staff and patient alike, and few expectant mothers in our part of this country can afford to stay in hospital longer than a week. Also the question arises whether such treatment will prove equally effective in exterminating the maternal disease, especially the early contagious stage.

Moore (1948) estimates that relapse occurred in 25–35% of those suffering from contagious syphilis who had been given 2·4 mega-units in three-hourly doses over seven and a half days. More recently (1949), advocating 10 injections of 0·6 mega-unit of procaine penicillin in aluminium monostearate, given daily or less frequently, he estimates that in early contagious syphilis a 10–15% relapse-rate may be anticipated. While appreciating that the patient need not be in hospital for the latter form of treatment, the relapse-rate is still high. Administration of aqueous penicillin three-hourly, or of procaine aluminium stearate penicillin daily, is designed to maintain an adequate blood-penicillin level; but it is by no means the unanimous opinion that penicillin treatment should be planned with this end in view.

With all due admiration for such enterprise, I prefer more conservative therapy and still adhere to the suggestions made in 1945 by Colonel L. W. Harrison *(then chief adviser in venereology to the* Ministry of Health) concerning the combined use of penicillin and heavy metals. Much has been written about the toxicity of arsenic and bismuth in pregnancy, but is it really so formidable? In the present series the very few who manifested intolerance responded remarkably well to *the early administration of dimercaprol.* This valuable drug has proved very successful when administered in

the outpatient department to all showing early signs and symptoms of intolerance to heavy-metal treatment.

It may be suggested that penicillin alone should be given during pregnancy, to protect the fœtus, and the arseno-bismuth part of the treatment should be deferred until pregnancy is over. A careful analysis of the problem of default in this department has provided overwhelming evidence against such a procedure, since a large proportion of pregnant women with latent infection fail to appreciate the gravity of the disease and default after confinement.

DIAGNOSIS OF INFANTILE INHERITED SYPHILIS

Except in virulent infection, signs of inherited syphilis are seldom well developed before the third week of life. A thorough clinical examination—especially of the skin, mucosal surfaces, abdominal viscera, and skeletal system—may fail to reveal any abnormality; nutrition may be normal or nearly so; yet the mother's history of inadequate treatment in pregnancy should warn the clinician that the infant may be infected. In such cases radiological investigation of the long bones shortly after birth may reveal widespread epiphyseal or periosteal abnormalities. Where serological findings in early infancy are giving cause for anxiety, radiological examination must be repeated even if the initial findings were negative. Further examination is similarly called for where there are radiological abnormalities but the serum test is negative. Intensive bismuth therapy during the last few weeks of pregnancy may cause increased density in the metaphyseal regions during the first six weeks of life, but repeated X-ray examination during the ensuing weeks will reveal a reduction in the density. If they become apparent later than the sixth or eighth week of life, bone abnormalities may be due to other conditions, such as rickets, familial hæmolytic anæmia, or erythroblastosis.

That the diagnosis may rest on serological examination alone is shown by a review of 58 consecutive cases of inherited syphilis in children under five years of age reporting at this clinic: of 39 under one year of age 12 (31%) showed no clinical evidence of the disease, and 7 of the other 19 were likewise clinically negative. In the absence of clinical or radiological evidence, however, an initial positive result with the Wassermann test (which is the one employed in this clinic) is possibly of no real significance. It may merely indicate the transfer of syphilitic reagin from the maternal to the fœtal circulation, in which case (*a*) the degree of positivity will not exceed that of the mother and (*b*) the result will become negative by the fourth month at latest. The infant which preserves its initial high titre or maintains a high fluctuating level beyond the early weeks of life, should be regarded as infected. Occasionally an infected infant appears healthy, has a negative initial blood test, but shows a steadily rising titre in the first few months of life.

SUMMARY

In 300 pregnant women, syphilis was treated with penicillin and also arsenic and bismuth. All the women received their scheduled dosage of penicillin (2·4 to 4·0 mega-units) and at least a quarter of their scheduled dosage of arsenic (4·65 g.) and bismuth (2·6 g.) before delivery, but in 33 cases the course of arsenic and bismuth had to be completed after the child was born.

As regards the outcome of pregnancy, the results were very satisfactory, even when the disease was virulent and treatment was begun late.

Penicillin with small amounts of arsenic and bismuth will protect the fœtus; but it may not fully cure the mother. A conservative form of treatment is therefore advisable, and it is suggested that all syphilitic pregnant women should have a full course of arsenic and bismuth as well as penicillin. Such treatment is well tolerated.

In the first few weeks of life a positive Wassermann reaction, in an apparently healthy infant, does not necessarily imply that infection has been inherited, and a negative reaction does not necessarily imply that infection has *not* been inherited. Repeated serological examination is necessary before reaching a conclusion.

EXCRETION OF INTRAVENOUSLY ADMINISTERED DEXTRAN *

LARS ENGSTRAND BERTIL ÅBERG
M.D. Stockholm Med. Kand.

From the Departments of Experimental Surgery and of Clinical Biochemistry, Karolinska Sjukhuset, Stockholm

PARTLY hydrolysed dextran was introduced as a plasma substitute by Grönwall and Ingelman (1944, 1945). These and other investigators, such as Thorsén (1947, 1949), have expressed the opinion that in vivo dextran is oxidised and broken down. Ingelman (1949) found that in rabbits given thyroid extract intravenously administered dextran disappeared from the blood more rapidly than usual; and he suggested that the increased metabolism accelerated the breakdown of dextran.

Several groups of workers, including Grönwall and Ingelman (1944, 1945), Bohmansson et al. (1946), and Bull et al. (1949), have reported that 20–30% of the injected dextran is excreted by the kidneys during the first 24 hours. Bull et al. (1949) concluded that the fate of the remaining 75% was still in doubt. By chemical quantitative and serological non-quantitative methods, they found that a small amount of dextran was retained in the body tissues, the lymph-nodes and spleen having the highest content. Even 56 days after administration, dextran could be detected serologically in the tissues. Certainly a small amount of dextran is normally taken up by the reticulo-endothelial system.

Bull et al. (1949) found no sign of enzymatic breakdown of dextran when it was incubated with blood, tissue extracts, and tissue suspensions. Indeed, taking into account the specificity of the diastatic enzymes of the body, enzymatic breakdown of dextran seems improbable; and this substance is probably eliminated in some other, unknown, way.

The high permeability of the liver sinusoids and of the capillaries of the intestinal wall led us to investigate the possible elimination of dextran from the blood in these organs.

EXPERIMENTAL RESULTS

For the analyses of dextran two methods of estimation were used:

1. Treatment of the media with glacial acetic acid and basic lead acetate. After filtration, the dextran content was determined polarimetrically, + 190° being taken as the specific rotation of dextran. Proteins were removed by boiling with Sörensen reagent.

2. The method described by Hint and Thorsén (1947) for estimating dextran in blood.

Uptake by liver and intestine.—Rabbits narcotised with 'Dial' were given dextran intravenously. Blood samples were withdrawn simultaneously from the carotid artery, from the portal vein by direct puncture and from the hepatic vein by means of a ureteric catheter introduced via the jugular vein. The dextran content was determined by the method of Hint and Thorsén (1947). No evidence was found of significant dextran uptake by, or clearance from, blood in the liver or intestine; and if there is any uptake in these organs, it amounts to about 0·5 mg. of dextran per ml. of blood passing through them.

---

* Communication to a staff meeting of the Surgical Clinic, Karolinska Sjukhuset, Stockholm, on Feb. 24, 1950.

Incubation of dextran with tissue extracts.—Incubation of dextran with blood and extracts of ground liver tissue (the latter produced by extracting the ground tissue for 24 hours with cold Ringer's solution at + 2°C under sterile conditions) at 38°C, revealed no breakdown of dextran, judged by dextran and glucose determination. Incubation with glycerin extracts of pancreas and pig's intestine for 96 hours gave the same result.

Excretion into the gastro-intestinal canal.—In fasting rabbits, under dial anæsthesia, the gastro-intestinal canal was divided at the pylorus and at the ileocæcal valve. The œsophagus was not tied off from the cardia. A cannula was inserted at the pylorus, and another into the lower end of the ileum. The dextran content in the stomach and small intestine was measured polarimetrically during 6 hours after the intravenous administration of 40 ml. of 6% dextran in physiological saline. In the gastric juice, about 190 mg. of dextran was found in about 110 ml. of juice, while about 26 mg. of dextran was found in about 35 ml. of intestinal juice; the intestinal juice contained no dextran during the first 3 hours of the experiment.

A cat (2·5 kg.), after fasting for 24 hours, was given 40 ml. (2400 mg.) of a 6% dextran solution intravenously. The distal part of the common bile-duct was ligated and the duodenum divided at the pylorus just proximal to the duodenojejunal flexure; and a cannula was inserted into the common bile-duct. The proximal end of the duodenum was closed. The œsophagus was not tied off at the cardia. Cannulæ were inserted into the stomach through its pyloric end and into the distal end of the duodenum; the gastric juice, bile, and pancreaticoduodenal juice were collected separately. The juices were taken up during 8 hours 50 minutes; and the dextran content was determined by the Hint-Thorsén method. Tests before the administration of dextran showed none to be present.

Altogether 0·24 g. of dextran was found in the gastric juice (8 ml.) and 0·44 g. in the pancreaticoduodenal juice (22 ml.). No dextran could be found in the bile (1 ml.). Thus in about 9 hours, 28% of the injected dextran was excreted into the alimentary canal.

CLINICAL STUDIES

Three subjects with no symptoms or signs of urinary disease, who had fasted for 15 hours, were given 800 ml. of 6% dextran intravenously. Histamine was given subcutaneously in the ordinary dose. The gastric juice was collected through a gastric tube during 4 hours. The results are shown in table I. Fæces collected during the following 24 hours contained no dextran. (In further experiments human fæces, diluted with two parts of physiological saline and filtered, were incubated with dextran for 46 hours at 38°C. The dextran was found to have been broken down fairly rapidly.)

TABLE I—RECOVERY OF DEXTRAN FROM GASTRIC JUICE IN MAN

Case no.	Gastric juice recovered (ml.)	Dextran in gastric juice	
		%	Total (g.)
1	95	0·18	0·17
2	43	0 26	0·11
3	54	0 09	0 05

ACUTE INTESTINAL OBSTRUCTION

Three cases of ileus in man were studied.

Case A.—A man, aged 43, was operated on for ureteri calculus. The operation, by the retroperitoneal route, wa completed without difficulty. On the 4th day after operatio *paralytic ileus and gastric atonia developed. On the 6th da* a gastric and an intestinal fistula were made. The patien was given 800 ml. of 6% dextran and large quantities o plasma, blood, and albumin each day. There seemed to b no great disturbances of the water and electrolyte balance On the 10th day we started to estimate the dextran conten of the urine and of gastric juice from the fistula. The result are shown in table II. On the evening of the 12th da di-isopropylfluorophosphonate (D.F.P.) was tried as a las resort to cure the atonia. An abundant outflow (3600 ml through the gastric fistula followed; this juice containe a very large quantity of dextran—3·6%.

TABLE II—RECOVERY OF DEXTRAN IN A CASE OF INTESTINA ILEUS

—	Days after onset of ileus						
	10	11	12	13	14	15	16
6% dextran intravenously:							
Volume (ml.) ..	800	800	800	800	800	800	8
Dextran content (g.)	48	48	48	48	48	48	4
Gastric juice from fistula:							
Volume (ml.) ..	1300	1100	3600	1400	2100	1750	—
Dextran content (g.)	0·1	0·1	100	5	0	0	—
Dextran in urine (g.) ..	15	5	0	12	14	12	—
Blood non-protein nitrogen content (mg. per 100 ml.)	75	75	150	192	172	210	23

Case B.—This patient was a man, aged 29, suffering from lead intoxication, ileitis, and ileus. Three days after on intravenous administration of 48 g. (800 ml.) of 6% dextran his gastric juice was collected through a cannula. It containe 0·74% dextran.

Case C.—A man, aged 42, suffering from ileus and anuria following an operation for cancer of the rectum, received 10 litres of 6% dextran solution in the course of nine days Three days after the last administration, 0·3% dextran was present in the blood, and 0·81% in the gastric juice.

EFFECT OF INTESTINAL OBSTRUCTION

In order to investigate the possible deleterious effect of a certain intestinal content of dextran in acute intestinal obstruction some preliminary experiments were performed on rats.

Under ether anæsthesia the small intestine of 30 rats was ligated with silk, under sterile conditions, about 10 cm above the ileocæcal valve. The animals were divided into three groups of 10. Into the intestinal lumen of these animals was injected through a fine needle 3 ml. of (*a*) physiological saline, (*b*) 0·5% dextran, or (*c*) 1% dextran. The mortality-rate and the total fluid content in the lumen of the stomach and small intestine at the time of death were determined. After death the proximal and distal ends o the stomach and small intestine were clamped and taken out After removal of the mesentery from the intestine, the flui in the lumen was allowed to run out into a measuring-tube

No significant difference was found in the mortality rate of the control animals and those injected wit dextran: 50% of the animals, died 20–24 hours afte the operation, and about 30% 30–36 hours after th operation. A quite significant difference in the intestina fluid content was, however, found; the content i animals injected with 1% dextran was one and a ha times or twice that in the control animals.

Possibly the rather short survival-time of all th animals obscures the eventual drawbacks of dextra The increase in the fluid content of the intestine of th animals injected with dextran suggests, however, tha dextran may cause harmful retention of fluid at thi site. In acute obstruction of the small intestine such a effect is undesirable.

CONCLUSIONS

From these experiments it seems that when dextran administered intravenously some that is not excreted rough the kidneys or deposited in the reticulo-dothelial system leaves the body after elimination into e alimentary canal.

This dextran is split, probably in the lower part of e intestinal canal. Elimination by this route cannot rm the normal body. With ileus, however, the effect dextran in causing accumulation of fluid in the testinal lumen is undesirable and probably harmful. cases of acute intestinal obstruction dextran must, erefore, be administered very cautiously.

GENERAL ANÆSTHESIA FOR BRONCHOGRAPHY IN CHILDREN

GEOFFREY L. WAY
M.R.C.S., D.A.
SOMETIME CONSULTANT ANÆSTHETIST

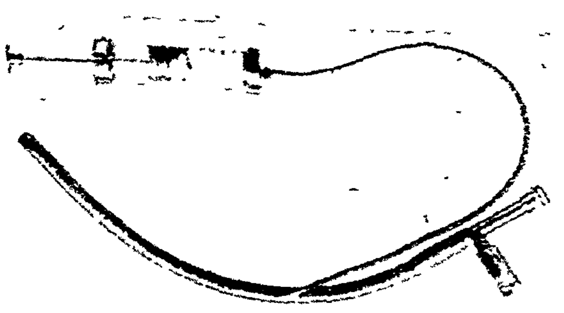
G. C. W. JAMES
F.R.C.S.E.
SURGICAL REGISTRAR

WARWICK HOSPITAL

THE modern treatment of bronchiectasis and other pulmonary disease by segmental lobectomy makes perfect bronchograms essential. In children these can only be obtained with certainty if the anæsthesia is good and there is coöperation between the surgical team and the radiologist.

Various methods of anæsthesia have been used for bronchography in children. One of the more recent is that devised by Baker (1941), which involved the giving of bromethol and hyoscine as premedication, and nitrous oxide, oxygen, and ether by a closed-circuit technique for the maintenance of anæsthesia, the iodised oil being introduced through a catheter passed down an endotracheal tube, and the circuit being made airtight by the introduction of a pharyngeal pack. This method, although satisfactory in some respects, has some shortcomings: an explosive mixture is used; no closed circuit can be guaranteed to be airtight; and the endotracheal tube is partially blocked by the introduction of the catheter.

In our hands other methods are unsatisfactory either because of the anæsthetic used or because of the methods of introduction of the oil. In devising a method of general anæsthesia for bronchography the main factors which have to be considered are an unobstructed airway, exclusion of the risk of an explosion, and quiet respirations. During the past two years in the chest unit at the Warwick Hospital a method has been worked out which fulfils these considerations.



The special intratracheal tube with Cobb's type endotracheal tube junction and syringe attached to side tube.

APPARATUS

A special endotracheal tube has been constructed (see figure) with a side tube for the introduction of the radiopaque fluid. This endotracheal tube has a special advantage in that the airway is in no way obstructed as when catheters are placed within an ordinary endotracheal tube.

The other requisites are an ordinary Boyle's machine without an ether bottle (London County Council 1936); a Cobb's endotracheal tube junction to allow suction to be carried out in an emergency; and the other instruments necessary for endotracheal intubation.

PREOPERATIVE TREATMENT

When a patient has sputum, it may be necessary for him to be treated as an inpatient before undergoing bronchography, because it is desirable to get rid of accumulated sputum if good bronchograms are to be obtained. Such inpatient treatment will consist of postural drainage twice a day for $^1/_2$–1 hour, penicillin inhalation, and expectorant mixtures.

TECHNIQUE

Anæsthesia is induced with 5% intravenous sodium thiopentone given slowly; 0·5–1·0 g. is given to children aged 4–12 years.

Direct laryngoscopy is performed, and the larynx sprayed with a few minims of 5% cocaine.

The special endotracheal tube well lubricated with 'Nupercaine' ointment is introduced into the trachea as far as the entry of the side tube, enabling the largest endotracheal tube to be passed.

The endotracheal tube is next connected with the Cobb's junction to the Boyle's machine (half-open).

The gases flowing through the Boyle's machine are nitrous oxide and oxygen in equal volumes passing over trichlorethylene (contained in the chloroform bottle). The patient is now ready for the injection of the radiopaque fluid down the side tube of the endotracheal tube, and it is possible to get the fluid in any particular lung area that is required, by placing the patient in the necessary position.

DISCUSSION OF TECHNIQUE

By using this method the risk of explosion is eliminated, because trichlorethylene is non-explosive below 25·5°C at the normal pressure of 740–760 mm. Hg in an atmosphere of 100% oxygen (Jones and Scott 1943). The airway is unobstructed by catheters and, so long as the iodised oil is given slowly, no obstruction is likely to occur. The respirations are quiet and slow. There is definite inspiratory and expiratory phases; this fact gives adequate time for X-ray exposures in the expiratory phase of respiration.

In an emergency the bronchial tree can be sucked dry and 100% oxygen given with such ease that no danger exists.

The patient can be readily moved into any position without any interruption of anæsthesia.

SUMMARY

A method of balanced anæsthesia for bronchography in children and a special *endotracheal tube* for the introduction of radiopaque fluids into the bronchial tree are described.

We wish to thank Mr. J. Leigh Collis, M.D., F.R.C.S., consultant thoracic surgeon, Warwick Hospital, for his encouragement and advice, and Dr. M. Israelski, of the X-ray Department, Warwick Hospital, for his coöperation. The endotracheal tube was constructed to our specification by Medical & Industrial Equipment Ltd., 12, New Cavendish Street, London, W.1.

Reviews of Books

Manual of the International Classification of Diseases, Injuries, and Causes of Death

Vol. II. *Alphabetical List.* H.M. Stationery Office. 1950. Pp. 524. 30*s.* the two volumes.

THOUGH the World Health Organisation's classification[1] has been obtainable in this country for the past year, the index volume has only lately made its appearance. But the delay seems to be amply justified by the fact that every effort has been made to compile a really full index of the diagnostic terms employed in British and American medical circles. Medical-Latin equivalents are also included for such English terms as are not easily recognisable by persons of non-English-speaking countries.

The new international index is thus much fuller than that of the American Standard Classified Nomenclature, though the numerous coded categories of the latter permit of much more differentiation between diagnoses. It may at last provide medical statisticians with what they have long needed—a diagnostic index so extensive that competent lay persons are able to assign correct codings to the most obscure diagnoses, with only occasional recourse to medical advice. And the value of statistics based on the W.H.O. classification will of course be considerably enhanced by the greater uniformity of interpretation that will be achieved by using this exceptionally comprehensive index for assigning cases to categories. Though vol. I classified all diseases, morbid conditions, and types of injury into 800 categories, there are over 40,000 entries in the main index of vol. II, which also has a separate index for causes of stillbirth and an additional index to external causes of injury.

Words are entered under both British and American spellings, and it has been deemed necessary to include many unsatisfactory terms in use, together with the names of certain surgical operations associated with specific diseases, since surgeons not uncommonly write down the name of the operation performed rather than the name of the disease necessitating it.' The compilers of the index have wisely added a useful introductory guide to its use.

The Pathology of Articular and Spinal Diseases

DOUGLAS COLLINS, O.B.E., M.D. Lpool, reader in clinical pathology, University of Leeds. London: Edward Arnold. 1949. Pp. 327. 35*s.*

THIS valuable book is the outcome of fifteen years' special interest in bone and joint pathology. Dr. Collins quotes Smith Petersen's findings that the new articular surfaces which are fashioned during the operation of 'Vitallium' cup arthroplasty become covered with hyaline cartilage, and concludes that repair and regeneration of articular cartilage are possible, though the process is not usually very active. Rarefaction of bone, he points out, is only a radiological term; for the accurate study of such a dynamic process as bone metabolism, the combined findings of the radiologist, biochemist, and pathologist must be correlated. He divides osteo-arthritis pathologically into four grades ranging from destruction of superficial articular cartilage to complete destruction of cartilage and eburnation of underlying bone. Marginal osteophytes, he points out, are made by the recasting of the joint under the influence of altered mechanical forces. Arthritis, too, he suggests, always results from altered mechanical conditions leading to loss of harmony between form and function. A straightforward account of gout is followed by a chapter on bacterial arthritis. Dr. Collins thinks that gonococcal arthritis always results from a light bacteræmic infection of joints, and joint tuberculosis almost always arises by hæmatogenous spread from the lungs; bone and joint tuberculosis are intimately connected. He maintains that there are many clinical types of rheumatoid arthritis and that there are no pathological grounds for distinguishing these as different diseases; indeed, in a later chapter he supports, on pathological grounds, the American contention that ankylosing spondylitis is a manifestation of rheumatoid arthritis. The specific lung changes in rheumatoid arthritis, described by other workers, are not mentioned, but he discusses Hench's work on the effects of 'Cortisone' and A.C.T.H. on rheumatic fever, rheumatoid arthritis, and other conditions. His clear thinking on osteo-arthritis of the spine is most welcome: he points out that osteophytes on the margins of the vertebral bodies are not true manifestations of osteo-arthritis—they are an incidental finding and no known clinical syndrome is associated with them. For the picture associated with such osteophytic outgrowths he uses the word osteophytosis, reserving osteo-arthritis for the condition that affects the diarthrodial *posterior intervertebral* joints

The book is beautifully illustrated by photographs, microscopical sections, diagrams, and reproductions of radiographs.

Biomicroscopy of the Eye

Vol. II. M. L. BERLINER, M.D., assistant professor of clinical surgery (ophthalmology), Cornell University, New York. *London: Cassell. 1949. Pp. 785. £12 12s.*

THE first volume of this work made it seem likely that we were at last to see an authoritative text on the slit-lamp appearances of the eye. This second, and presumably concluding, volume fully bears out that promise. It deals with the iris, lens, zonule, and vitreous, and with what little has been achieved with fundus examination. In comprehensiveness it challenges comparison with the classical volumes of Vogt, but most readers will probably prefer Berliner because the text is smoother and less broken up by case-histories. He gives accounts of some conditions which are only doubtfully distinct clinical entities: for example, the description of gonococcal iritis leaves the impression that slit-lamp appearances support the view that this is a distinct entity. It is however fair to add that in such accounts he is quoting observations by others rather than giving a personal view. Where slit-lamp findings have clarified clinical pictures, his detailed descriptions are beyond criticism, and he is catholic enough to include accounts of axial cataract, though, like most slit-lamp authorities, he is apparently unconvinced of its existence. The 82 colour plates carried by the two volumes are in themselves an excellent atlas. The book is likely to remain, for many years to come, the most balanced exposition of knowledge on the biomicroscopy of the eye and the definitive work in English.

What are You Doing Here? (Edinburgh: International Publishing Company. 1950. *Pp.* 128. 10*s.* 6*d.*).—Mrs Cecil G. Trew gives a short account of her experiences as a surgical artist with the Army in Europe, during three months in the winter of 1944. As the book is in the nature of a personal record for friends, it does not describe the work she did—though some little sketches of war scenes illustrate the text.

Modern Treatment Year Book, 1950 (Published for the Medical Press by Baillière, Tindall, and Cox. 1950. Pp. 346 17*s.* 6*d.*).—This annual survey of modern treatment again makes its welcome appearance under the imprimatur of Sir Cecil Wakeley and a team of experts. The selection of articles covers a wide field of medical and surgical practice to keep the general practitioner well informed. He may not himself be able to carry out all the forms of treatment recommended, but an intelligent knowledge of new procedures is bound to be useful to him.

List of Fungi Recorded and Pathogenic for Man and Higher Animals in Britain (London: Cambridge University Press. 1950. 2*s.*).—Dr. G. C. Ainsworth's list[1] is an ample and selective compilation of the bibliography of pathogenic fungi of medical and veterinary interest found in Great Britain in both indigenous and imported disease. The fungi are arranged in taxonomic groups and under each name is given a list of references, many of which are amplified by notes indicating the principal features of the paper. Two indexes are included—one giving the hosts with their associated parasites, and the other the list of fungi in alphabetical order, with the authorities. Dr. Ainsworth's painstaking work should prove of great value to writers of papers on fungus diseases.

LONDON: SATURDAY, JUNE 10, 1950

Unification of Government Medical Services

THE appointment of Sir JOHN CHARLES as chief medical officer to the Home Office as well as to the Ministries of Health and Education is a welcome innovation.

In this country the arrangements for medical advice to Government departments have been made piecemeal. As each department has felt the need for such advice it has produced its own organisation and recruited its advisers—with little apparent reference to the medical advisory structures existing in other departments, and with all kinds of anomalies of salaries and status. We have never had a unified service such as has existed in the United States for 150 years in the U.S. Public Health Service; nor have we adopted the Australian system whereby all doctors in the service of the federal government are medical officers of the federal department of health, lent by its director-general—who must himself be a doctor—to the other departments. From the time when Sir JOHN SIMON was appointed central medical officer to the Board of Health in 1855, the number of our Government departments, and their need for medical advice, has increased until today there are no less than twenty such departments with medical advisory structures of various types, the large majority including whole-time medical officers. The first small step towards unification was attempted by the Ministry of Health Act in 1919, which laid down that medical inspection and treatment of school-children should be transferred from the Board of Education to the Ministry of Health. This has never been carried out; but, perhaps because of Sir GEORGE NEWMAN's intimate connections with the board, the chief medical officer of the Ministry of Health was appointed also to the post of C.M.O. of the Board (now Ministry) of Education. For the next 30 years the position was unchanged; and, though Sir WILSON JAMESON's efforts to achieve liaison and coördination were successful, his known wish for unification was unfulfilled. Now the ice is perhaps again beginning to melt, and it is logical that the Home Office, with its special commitments for the care of children and for civil defence, should be the first to come into closer relation with the Ministry of Health.

The advantages of a unified medical service, say on Australian lines, would be manifold; and opinions in its favour have been expressed by professional bodies including the British Medical Association. Even admitting that some of the separate services are highly specialised, the pooling of doctors in one service would ease the problems of temporary shortages of staff and would facilitate secondment for all sorts of desirable purposes, not only within Great Britain but for the Colonial and other posts which are now so hard to fill. Considerable overlapping, as for example between Labour, National Insurance, Pensions, and Health on such matters as reablement and industrial hygiene, might be avoided; indeed many difficulties of the National Health Service would have been less if reform of the Government medical services could have been introduced at the same time. A unified approach and machinery for salary and other establishment questions would become possible, and it would be an advantage to all parties if the doctors in the smaller departments, when they feel frustrated by lay chiefs, could turn for guidance and support on professional matters to a professional chief outside their department. Admittedly, at the previous rate of progress we could not expect such unification much before A.D. 2450; but a Government which has displayed so much interest in medical organisation could choose no better time than the present for setting this part of its house in order.

The Growth Hormone

IT was not easy to realise, when listening to Prof. HERBERT M. EVANS's lively address at the Royal Society of Medicine on May 24, that this young-old man is one of the pioneers of modern endocrinology. Nevertheless, it was EVANS and LONG[1] who in 1921 injected a simple saline extract from the anterior pituitary lobe into young rats and produced experimental gigantism. This was the first time that the administration of any extract of the anterior lobe had been shown experimentally to affect an animal. It was two years before ALLEN and DOISY[2] studied the œstrous cycle of the mouse by the vaginal-smear technique, thus providing a sufficiently delicate method of biological assay of œstrogens to form a basis for the development of modern knowledge of the ovarian hormones. It was six years before ASCHHEIM and ZONDEK[3] discovered a potent gonadotropin in the urine of pregnant women and thus pointed the way to the present views on the relation between the pituitary, the ovaries, and the uterus in the menstrual cycle and in pregnancy. It was eight years before LOEB[4] injected an anterior pituitary extract which produced thyroid enlargement in guineapigs. Not only does the credit for the first discovery of the growth hormone belong to EVANS, but most of the subsequent work which eventually led to the isolation of the pure hormone[5] was done in his institute in the University of California, where careful studies have since been made of the properties and functions of this compound.

The growth hormone (or "somatotropin" as EVANS prefers to call it) is a protein not easily soluble in water and readily destroyed by pepsin, trypsin, and boiling. Its molecular weight is 44,250, and the protein, which contains no prosthetic groups, has 369 peptide linkages. The presence of the amino and tyrosine groups is essential for growth promotion. The functions of this hormone have been intensively

studied in animals in the past six years, though no observations have yet been made on the human subject. It might be expected that one of its main effects would be on skeletal growth. After hypophysectomy a calcium barrier, the "closing membrane," appears between the epiphysis and diaphysis, and though some epiphyses never unite, longitudinal growth is prevented by this barrier. Injection of growth hormone leads to the immediate disappearance of the closing membrane and initiation of active chondrogenesis and osteogenesis. In the temporomandibular joint, for instance, the entire head of the mandible is converted into cartilage cells. Alkaline phosphatase has been shown to be indispensable in bone-formation,[6] and it is not surprising that there is a rise in the plasma alkaline-phosphatase level after administration of growth hormone. There is also retention of inorganic phosphorus.

Ever since the classical work of HOUSSAY [7] it has been recognised that the anterior pituitary exerts a profound influence on carbohydrate metabolism. The pituitary's adrenocorticotropic hormone (A.C.T.H.) stimulates the adrenal gland to secrete the group of cortical hormones, the 11-oxysteroids, consisting of KENDALL'S Compounds E ('Cortisone') and F and possibly factors present in the "amorphous fraction," which increase gluconeogenesis (the conversion of proteins to sugar) and therefore increase the storage of sugar in the liver as glycogen and also cause a rise in the blood-sugar level and sometimes glycosuria. This effect is entirely independent of any action on the islets of Langerhans. In contrast, the effect of growth hormone is intimately associated with pancreatic function, and it has been shown that pure growth hormone stimulates the β-islet cells. In some circumstances this leads to secretion of insulin with subsequent hypoglycæmia. On the other hand, the studies of Prof. F. G. YOUNG and his colleagues have made it clear that protracted administration of pituitary extracts containing growth hormone may induce permanent diabetes associated with degeneration of the β-cells. In his Sidney Ringer lecture at University College Hospital, YOUNG pointed out that, in some species, growth hormone exhibits growth-promoting properties in the tissues of young animals, which are primarily attuned to growth, whereas in adults of the same species extracts containing the hormone produce not growth but diabetes. This fact may have clinical significance, for a syndrome has been recognised in which pregnancy gives rise to maternal "obesity" and large babies (usually with a birth weight of over 10 lb.), and later in life these mothers may develop diabetes.

Growth hormone also exerts a fundamental effect on protein metabolism. A.C.T.H. is a "protein-waster": through the agency of 11-oxysteroids it mobilises protein from the skin, the matrix of the bones, and the peripheral vessels to convert it into glycogen. Growth hormone is a "protein-sparer": it produces nitrogen retention and a positive protein balance. Rats treated with growth hormone and maintained on a constant diet put on weight. They look "fat" compared with their control litter-mates kept on the same diet, but analysis of the carcass reveals that their "obesity" is due to increase in the protein content and consequent water retention, and that the fat content is low. YOUNG suggests that there is a depletion of their fat stores, the fat being "burnt" to supply the necessary energy for retaining protein and building it up into muscle and other tissues to account partially for their increased weight. Nitrogen retention leads to water retention, and the fluid content of their tissues is significantly higher than in the control animals. It is possible that some types of human "obesity" belong to this metabolic pattern. Clinicians often find difficulty in avoiding the conclusion that the "obesity" in some of their patients is largely due to fluid retention though the physiologist may have little evidence of it. Postpartum obesity, or obesity occurring during pregnancy and increasing thereafter, is a well-recognised syndrome. This may perhaps be associated with over-activity of growth hormone during pregnancy; and indeed, the maternal obesity—large baby—diabetes syndrome already referred to suggests that this overactivity does sometimes occur in pregnancy. In these circumstances weight would increase without any change in appetite or food intake.

Another property of growth hormone is its action on lactation. FOLLEY and YOUNG [8] have shown that administration of pure growth hormone to cows with failing lactation increases the milk yield. This method appears, moreover, to be more efficient than treatment with prolactin or with iodinated proteins. YOUNG regards lactation as essentially a manifestation of "growth."

Thus a good deal is known about the experimental effects of pure growth hormone in animals. Its clinical potentialities however have not yet been probed. Crude anterior pituitary extracts with potent growth-promoting properties in animals have been used in cases of pituitary infantilism, achondroplasia, and other types of dwarfism, but they have been almost uniformly disappointing. Though pure somatotropin was isolated six years ago, none has yet been obtainable for clinical use. This is understandable, since the yield of material from animal pituitaries must necessarily be small in terms of human dosage. Furthermore the clinical indications will probably be limited. Dwarfism due to pituitary failure is rare, most cases being a result of constitutional or genetic defect. Nevertheless, when clinical trials are practicable the results will be watched with interest.

Blood-cells under the Electron Microscope

WE have become familiar with the appearance of minute bodies like viruses or the smaller bacteria when photographed through the electron microscope at high magnifications. The viruses are mostly too small to be seen with the optical microscope, so the electron microscope is particularly suitable for detecting them and rendering their profiles visible. But the electron microscope can also be used for studying the details of larger objects if they can be made thin enough, can be mounted on a sufficiently thin and non-distorting support, and can be properly dried.

[8] Young, F. G. *Biochem. J.* 1945, 39, 515. Cotes, P. M., Crichton, J. A., Folley, S. J., Young, F. G. *Nature, Lond.* 1949, 164, 992.

This seems a formidable programme for blood-cells, but it has been solved in several ways. In all the methods the cells are supported by a film of 'Formvar,' a plastic material. When a glass coverslip is coated with a thin film of formvar, leucocytes and red cells will stick to the film, and. even more important, the leucocytes will flatten out so that their cytoplasm is extended as a thin layer. The leucocytes on formvar films can be fixed and dried in various ways, and the film can be transferred to the object screen of the electron microscope without distortion. The first electron photomicrographs of platelets were published in Germany in 1939[1]; more recently most of the hæmatological work with the newer techniques has been reported from the U.S.A. and France.

The method adopted by Rebuck and Woods[2] was to scrape small lesions on the forearm skin of volunteers exposing the corium. Formvar-coated coverslips were kept in contact with the lesions for different periods, during which leucocytes migrated and stuck to the formvar. The leucocytes were then fixed by rapid freezing and dehydration in vacuo. Tissues were also used in the same way to make imprint preparations on formvar films. After fixation the films were transferred to electron microscope screens and no metallic shadowing was added. The photographs of cells treated in this way show much detail in both cytoplasm and nucleus. In a small histiocyte or monocyte with a horseshoe-shaped nucleus, at a magnification of × 5400, the nucleus appears very distinctly as a black network of thick strands and many black masses with scattered white areas in the interstices; the cytoplasm appears as a much finer network with the white interspaces occupying the larger area. At × 18,000 it is clear that the structure of the whole cell is an interlacing network, the nucleus being constructed of relatively coarse strands and fibrils with few interstices, and the cytoplasm of relatively fine strands with large spaces between them. At × 94,000 the blurred picture, like lumps of cotton-wool on a black background, shows that the fibrillar crosspieces are anchored to, but do not cross, the nuclear membrane. The granules of neutrophil granulocytes, which were indistinct under the optical microscope, when magnified 18,000 times by the electron microscope are clearly seen as rounded, oval, or rod-shaped objects: at × 72,000 they are as much as an inch across. Eosinophil granules are spherical and larger still. Pictures of lymphocytes at × 5400 are not very clear, though the nuclear pattern of coarse chromatin masses can be made out and contrasted with the fine chromatin pattern and clearly demarcated nucleoli of immature forms. For some later pictures, instead of freeze-drying, Rebuck[3] fixed the cells by immersion in osmic acid and drying in air. In these the nuclear structure is rather obscure though it is definable up to × 6800, the cytoplasm is uniformly black, and specific granules are poorly defined.

The French workers have made much use of "shadowing" the cell structure with a vaporised heavy metal, thus producing relief pictures like the well-known ones of viruses. As in these the nucleus appears as an amorphous white mass, only cytoplasmic detail can be studied, but these details are remarkably clear even at × 15,000. Bessis[4] studied blood-platelets by this method and showed that they start as rounded forms but later throw off many long thin processes like the dendrites of nerve-cells. Their cytoplasm contains numerous minute bodies—at × 20,000 they are about 1 mm. across—which remain after mechanical destruction of the platelets. Similar bodies were found in the cytoplasm of polymorphs and they are presumably connected with the structure of protoplasm. Bernhard and colleagues[5] preferred a slightly different technique. In heparinised blood, kept at 37°C, they immersed formvar-coated coverslips for varying times. Leucocytes stuck to the formvar and spread out, whereas rinsing with saline removed all the red cells. The preparation was then fixed in osmic acid vapour and dried over phosphorus pentoxide. They also added metallic shadowing; so their preparations show cytoplasmic detail only. The most striking of their findings concerns the cytoplasmic dendritic processes that leucocytes throw out under these conditions. On a film that has been immersed in blood for 10 minutes a polymorph × 6300 appears as a roughly oval cell about 7 inches long with a few dendritic processes. After immersion for half an hour many very long dendritic processes appear; these are very fine branching filaments with thickenings at the junction points, and the processes from one leucocyte sometimes appear to anastomose with those from other leucocytes. Lymphocytes form much fewer dendrites and they are short and stubby, more indented than branched, whereas monocytes, even on films immersed for 20 minutes, show no cytoplasmic protrusions at all.

How far are these appearances artefacts, produced by the preliminary preparation? The network pattern of the cells dried at low temperature in vacuo may well be nearer the real thing than the structure seen after osmic acid treatment, since such chemical fixation is likely to alter the arrangement of molecules in the protoplasm. In dried frozen preparations ice-crystals may be formed, and it is difficult to say how far the reticular structure observed is a result of these. Rebuck and Woods[2] point out that the reticular structure can also be seen in cells that have not been frozen, and such appearances certainly fit in with the present-day view that protoplasm is composed of a framework of linear molecules. So far the electron microscope studies of blood-cells, though they have perhaps added to our knowledge of the minute structure of the cells, have produced nothing which is applicable to disease or which immediately alters our views on the significance of the stained artefacts we are accustomed to use for diagnostic purposes. Since electron microscopy yields information especially about the cytoplasm, this is not really surprising. Other methods of studying cytoplasmic detail, such as supravital staining and phase-contrast microscopy, have also contributed little to the refinement of diagnosis. For the time being, at any rate, the electron microscope is not a desirable or necessary addition to the equipment of the clinical hæmatology department. Finances being as they are, this is just as well.

Annotations

DISEASES OF ADAPTATION

From ancient times many of the great clinicians have been well aware that the patient's emotional life has something to do with illness. Physicians such as Sydenham and Heberden studied the whole man. But the structural concept introduced by Virchow led to the separation of illness from the mind, and a consideration of disease as merely a disorder of organs and cells. With this separation of disease into different pathological entities, physicians became specialists, each attending to one or other of these diseases. As E. Weiss has put it, "medicine then interested itself in the study of the organism as a physiological mechanism impressed by blood chemistry and other methods of investigation, but unimpressed and even holding in contempt the psychological background of the patient which was not considered as scientific as the results of laboratory studies." But fortunately there are many signs that physicians are again realising that in health and disease there is a need to study man as a whole, the complete man. Thus, in our last issue Ranyard West urged that every doctor should ask himself Halliday's three questions: (1) Why did the patient take ill when he did? (2) What sort of man is it that has got this illness? and (3) Why is this *particular organ or function* affected? We have to discover how somatic changes occur as a result of psychogenic derangement of function, or of stress in general.

The great part that hormones play in the animal economy is generally recognised. How widespread is the influence of the hypothalamus on the endocrine system, and how the secretion of the anterior lobe of the pituitary body, and hence indirectly the activity of the thyroid gland and adrenal cortex, are under the control of the nervous system, was demonstrated in 1947 and 1948 by G. W. Harris and J. D. Green, while D. M. Hume in 1949 showed that the anterior hypothalamic centres form an essential link in the activation of pituitary adrenocorticotropic (A.C.T.H.) secretion following conditions of stress as well as administration of adrenaline. Upon nervous stimulation or contact with circulatory adrenaline, a humoral substance appears to be secreted by cells of the anterior hypothalamus which stimulates A.C.T.H. secretion; and George Thorn says that through this neurohumoral system the adrenal cortex may be activated to secrete 11·17-oxysteroids by a number of non-specific stresses and emotional factors. In 1948, in the Heberden oration, Philip Hench drew attention to the reversibility of rheumatoid arthritis, a reversibility which may occur spontaneously, therapeutically, or accidentally. He argued that the disease is possibly a biochemical disturbance of an unknown nature which is transiently corrected by some biological change. He restated his belief that rheumatoid arthritis is not necessarily a relentless chronic progressive disease. In 1949, with Kendall, Slocumb, and Polley, he demonstrated the dramatic effect of 17-hydroxy-11 dehydro-corticosterone (Compound E), later to be known as 'Cortisone.' This was a great advance in therapeutic research, extended by the work of Thorn on the use of A.C.T.H. These hormones, however, do not seem to alter the fundamental cause of the inflammatory changes which characterise certain of the rheumatic diseases.

Clinical experience, sometimes in contrast to statistical survey, has suggested that stress does precede the onset of rheumatoid arthritis, and often exacerbates the disease when this is established. Whether the response of the adrenal cortex to stress is merely a trigger mechanism setting off a train of events, already prepared in the body, or whether some permanent imbalance between the various corticosteroids becomes the dominant factor in the causation of arthritis, is not known. A possible and partial explanation was offered in 1946 by Prof. Hans Selye when he produced arthritis in animals by the administration of deoxycortone acetate.

In the Heberden oration on the Rheumatic Diseases as Diseases of Adaptation delivered to the Heberden Society on Friday and Saturday of last week, Professor Selye described the theory he terms "the general adaptation syndrome," and discussed his experimental work on animals and its application to clinical medicine. The diseases of adaptation he attributes to a breakdown of the hormonal adaptive mechanism. The organism reacts by means of a common hormonic mechanism, in which the adrenal cortex is primarily concerned, to a variety of stressor agents—traumatic stimuli such as heat, cold, X rays, infection, and emotional stress. Exposure to stressor agents will cause a triad of disturbances, thymicolymphatic involution, gastro-intestinal ulcers, and adrenocortical hypertrophy. He described how stress may be followed by an "alarm" reaction, a stage of resistance and a stage of exhaustion. Both damage and defence reactions take place. These, he said, are those mediated by either glucocorticoids or by glucocorticoids plus an *x factor* which liberates minerocorticoids. He emphasised the importance of the glucocorticoid and minerocorticoid balance in health and disease. Dependent on the severity and duration of the harmful stimuli, on sodium intake, and other factors, lesions resembling nephrosclerosis, periarteritis nodosa, and the "collagen" diseases are produced. Diseases such as peptic ulcer, hypertension, and "allergy" are determined by a disturbance in this adaptive mechanism. Finally he pointed out that, in his animal-experiments, deoxycortone caused a variety of lesions simulating rheumatic and other diseases according to the "conditioning factors" and the "target organ"; the therapeutic success of starvation in rheumatism, and the effect of pregnancy and jaundice are he believes, due to their acting as stressor agents which liberate A.C.T.H. endogenously.

Professor Selye remarked that the purpose of a theory in medicine is to act as a guide. Whatever the ultimate fate of the theory he has so fascinatingly developed, it may well point the way to the solution of at least some of the medical and social problems of stress.

RENAL TUBERCULOSIS IN CHILDHOOD

Tuberculosis of the kidneys is not a common manifestation of the disease in children as seen in the pædiatric clinics. Müller describes, in a monograph,[1] 56 examples found among 10,000 tuberculous children seen in the clinic of Wangen-im-Allgän, during 1928–46, and points out that, though uncommon, the condition is part of a generalised tuberculosis. It is discovered in the pædiatric clinic more often than in the urological department, and is prone to manifest itself differently in the two clinics: in only 10 cases did it appear in his series as a renal lesion, the rest of the patients being brought for endothoracic or skeletal tuberculosis. As a result of his experience, he believes that miliary tuberculosis can heal—a fact which he considers is insufficiently recognised. The primary foci are commoner in the lung than in the alimentary tract and the source of the infection must generally be sought in the family. Severe open pulmonary tuberculosis and severe open renal tuberculosis appear to be mutually exclusive. The development of renal tuberculosis in childhood may be slow, and Müller quotes two instances in which

[1] Müller, R. W. *Über die Nierentuberkulose im Kindesalter.* Stuttgart: Thieme. 1948. Pp. 49. D.M. 6.30.

6–6½ years elapsed between the first demonstration of tubercle bacilli in the urine and the appearance of bladder symptoms. He emphasises the importance of routine urine analysis, and tuberculin tests, in diagnosis, but finds blood-sedimentation rates of no special significance. Tubercle bacilluria is by no means the rule in this disease. The indication for removal of the kidney depends in his view on the presence of extrarenal foci, but the prognosis of the disease is in any case bad and results of the operation have not been encouraging.

JOINT CONSULTATION

MANY hospitals have already arranged for joint consultation between management and staff; but the extent to which this arrangement is used, and the composition of the consultative committee, varies from one hospital to another. Such committees are now to be set up in all but the smallest hospitals; and their constitution and function (described by Mr. Dalton on p. 1086) are to be standardised.

In some respects the new scheme differs from those adopted in industry. Thus in industry the national approach has been largely discarded in favour of a more subtle one that is believed to evoke a better spirit of coöperation. In industry, again, it is now usually accepted that management and staff should be equally represented; and the Ministry of Health's suggestion that the management side should perhaps have fewer representatives (recommendations being reached "by agreement between the two sides") may prove too optimistic since in committees of this sort the two sides are not always unanimous and a show of hands is sometimes needed. The General Whitley Council, in drawing up the model constitution, seems to have been undecided as to the side on which senior officers should be represented. The machinery for producing the material on which the committee is to deliberate has not been described: nor that for the dissemination of information about the committee's findings. One is left wondering why five divisions of staff were selected for representation instead of the customary six; and no provision seems to have been made for the automatic resignation of delegates who neglect to attend meetings. However, these possible defects are less important than they would be in industry: for in hospital interests are less sharply opposed. We have every hope that the scheme will prove of real value.

SEX EDUCATION IN THE CINEMA

IN the last few weeks two American sex-education films have been exhibited in London, both of them fictional and designed to emphasise the dangers of ignorance, and both with the sponsorship of a number of social-hygiene organisations. Despite the soundness of the general idea, neither picture was particularly successful in doing what it attempted, and the main justification for showing them is that nothing better is available. American taste in presentation, and in sugaring the documentary pill, is badly out of key with the English audience; the antics of bobby-soxers in trouble strike very few sympathetic notes in our experience; and animated diagrams of the uterus and fallopian tubes, introduced with music, have little recognisable connection with the problems of conduct involved. The main criticism is not that made by the Public Morality Council when *Should Parents Tell?* was shown, but the risk that a useful kind of hygiene teaching may be made ridiculous through bad management. The suggestion in both these films that elementary physiological knowledge—rather than an adult attitude—is the main aim of sex education is sufficiently misleading in itself to be harmful.

A better idea of the kind of film which might be valuable is given by the series of short Canadian pictures, designed to illustrate various kinds of immaturity and personality defect, which were recently televised. The semi-fictional documentary could undoubtedly be used in sex education, both for adults and adolescents, but in a matter where cultural attitudes differ so widely films made in America are heavily handicapped from the outset. Documentaries with human interest are perhaps the one type of film which English studios handle superlatively well; and our own attitude to sex education lacks most of the emotive overtones so prominent in the American mind. If we can imagine a collaboration between the narration of Wilfred Pickles or the Radio Doctor, the script-writing of Mrs. Nesta Pain, and the production of *The Blue Lamp*, we can certainly envisage social-hygiene films which would be neither over-inhibited nor sensational, nor unintentionally funny. A high-level collaboration of this kind, adequately financed, would be worth any number of animated physiological models, and is certainly badly needed. It is an undertaking which might commend itself to one of the larger public foundations.

SOCIAL CLUB THERAPY

THE difficulty of every emotionally or mentally ill patient is to fit into society; but if he is ever to learn how to do this, he must have some society to fit into. For over ten years Runwell Mental Hospital has provided inpatients with a social club which they manage themselves, men and women together, and which gives them the chance of sharing many activities—such as indoor and outdoor games, social gatherings, and dramatic and other forms of entertainment. Many mental hospitals nowadays also sponsor outpatient clubs, where discharged patients can meet and gradually regain their social ease. Carrying the principle further, the Institute of Social Psychiatry, has established over the last ten years, about a dozen clubs for various kinds of psychiatric and asocial patients. The institute also founded the Social Psychotherapy Centre and Day Hospital, now a part of the National Health Service. This centre, which held its first visiting day on June 6, has a turnover of about 500 patients in the year, and carries a staff of some eight or nine part-time physicians, a psychologist, an occupational therapist, and psychiatric social workers. Patients are treated individually, in groups, or by occupational therapy, according to their needs, and they also become members of an appropriate social club. Thus a shy patient, whose heart fails at the thought of strange company, is offered a club where all the members are shy—a prospect which relieves his anxiety at once. The clubs vary in membership from 25 to about 70, and patients are encouraged to bring their wives or husbands to the gatherings. It is found that in the give-and-take of social intercourse at the clubs patients often learn to resolve their conflicts, find new outlets, or take the responsibility which they have been shunning or unconsciously desiring. At the same time they may be attending the centre, for individual or group psychotherapy. This treatment is in the main analytical; but the approach is liberal, for some of the staff are Freudians, some Jungians, while Dr. Joshua Bierer, the medical director, is an Adlerian. Since good results are claimed for all three methods, it seems that something more—or other—goes to the successful treatment of these patients than a particular theory of the inner causes of their illness. Among the group sessions held, one course perhaps deserves special notice. This is an instruction group in biophysiology, mainly for patients with anxiety states, in which they are taught the physical mechanisms which lie behind such things as tachycardia, an overactive gut, trembling fits, breathlessness, and sweating—symptoms which can be terribly alarming to those who believe them always to be the expressions of dangerous physical illness.

Child-guidance sessions are also held, and children with behaviour difficulties come daily for play therapy.

Since the principle followed with every case is to attack the difficulty from as many directions as possible, the parents are invited to join one of the clubs, in the belief that if they can better their own relations to society they will prove better society for the child; and so it is apt to turn out. The centre is in a pleasant house in Hampstead, and is open all day.

TERRAMYCIN

SUBSEQUENT work on the antibiotic terramycin, produced by *Streptomyces rimosus*, is justifying the hopes of its discoverers, Finlay and his colleagues,[1] of New York. It is a crystalline compound which forms salts with both acids and bases; these are stable at room-temperature and may be kept without loss of potency for at least a year. Pharmacological tests and limited clinical trials by Herrell et al.[2] at the Mayo Clinic have confirmed that the new antibiotic has a wide bacterial spectrum in vitro and in vivo, being effective against gram-positive and gram-negative organisms and some rickettsiæ and viruses. In many respects terramycin is comparable in its range of activity to 'Aureomycin,' and like aureomycin and chloramphenicol it is effective by mouth. When given in doses of 500–750 mg. six-hourly (i.e., 2–3 g. daily) it can be detected in active concentrations in the blood, cerebrospinal fluid, pleural cavity, bile, urine, and fæces. It also passes the placental barrier, and so can be given in pregnancy for the treatment of mother and fœtus. Terramycin is relatively non-toxic, and according to Herrell et al. the diarrhœa, nausea, and vomiting that sometimes occur when it is taken on an empty stomach can be overcome by giving it in a capsule with milk. The only other side-effect observed is glossitis, which has also been described with other antibiotics taken by mouth. With ordinary dosage the terramycin excreted in the fæces may produce concentrations as high as 2·5 mg. per ml., which will have much the same effect on the bacterial flora as the oral administration of aureomycin; clostridia, streptococci, and coliform organisms disappear and the fæces become odourless. Considerably higher concentrations are attained in the urine with terramycin than with aureomycin after comparable dosage by mouth.

Among the organisms sensitive to terramycin are pneumococci, *Staph. aureus*, hæmolytic and non-hæmolytic streptococci, *Strep. fæcalis*, gonococci, *Hæmophilus influenzæ*, *H. pertussis*, *Br. abortus*, *suis*, *and melitensis*, *Klebsiella pneumoniæ* (Friedländer's bacillus), *Bact. coli*, *Ps. pyocyanea*, *Pasteurella tularensis*, spirochætes, the rickettsiæ of typhus, Rocky Mountain spotted fever, Q fever, and rickettsial-pox, and the viruses of primary atypical pneumonia, lymphogranuloma venereum, and influenza. The preliminary clinical trials published by Herrell et al.,[2] King et al.,[3] and Hendricks et al.[4] in the United States show that the conditions responding satisfactorily to terramycin include pneumococcal pneumonia; urinary tract infections due to *Bact. coli*, *Ps. pyocyanea*, and streptococci; bacteræmia due to susceptible organisms; lung abscesses; follicular tonsillitis; and erythema multiforme. Hendricks and his colleagues have tried it in syphilis, gonorrhœa, and granuloma inguinale. After two doses of 1–2 g., with 6 hours between, the cure-rate claimed in gonorrhœa is 80–100%. It is too soon for any opinion on the ultimate value of terramycin in syphilis, but it will cause the spirochæte to disappear from the local lesion in 24–48 hours and a negative serological test is obtained a month after treatment. Only 2 patients with granuloma inguinale were treated; but in both of these the lesions had cleared by the third day.

Further clinical trials with terramycin are under way or in course of publication. It appears to be a most useful antibiotic with a wide range of activity, though owing to the dollar situation it may be some time before much is obtainable in this country.

LOOKING AT YOUNG CRIMINALS

CRIME is so troublesome for everybody that it deserves to be studied from as many standpoints and by as many good minds as possible. Sir Leo Page's book[1] on the young lag has a unique value of its own, for it contains case-histories of general interest, and a good deal of constructive comment on legal and penal methods. It is, moreover, a picture of the author, a humane, intelligent, and experienced man in contact with convicted criminals and attempting, with some success, to understand and help them. He has no special training in psychology, but is quite willing to profit from any insights it provides, so long as they do not conflict with "common sense." He specifically repudiates retribution as an improper and untenable theory of punishment. He is willing to learn, but unwilling to be bullied by experts. His attempts to make contact with delinquents, even when their attitude makes him indignant, are both painstaking and genuinely humane. Sexual offences leave him bewildered and disgusted. What the psychiatrist can get from this book is a picture of the best type of magistrate or prison governor that he will ever have to convince of the soundness of the interpretation he advances—a man who has his own ideas of the causation of crime in phenomena like irreligion, lack of discipline, and shortage of boys' clubs, and who makes serious efforts to verify them by observation. Sir Leo Page's viewpoint, quite apart from the respect commanded by his experience, is one which has to be kept constantly in mind.

If we contrast it with the method used by Mr. D. H. Stott in his recent survey[2]—based on a lower age-group—Sir Leo's method of approaching crime becomes easier to evaluate, and the criticisms of it which most psychologists would make become clearer. Sir Leo finds it impossible, in a case which is "as plain as a pikestaff," to swallow psychological suggestions of a greater underlying complexity. It is obvious, and a matter of common knowledge, that prostitutes rob their clients because they like money and want to have more of it—what more is there to be said? It is equally obvious that irreligion causes crime. This is a viewpoint which commands great sympathy, particularly when ill-judged theorising is rife in medical reports; but it is one which a fuller knowledge of the evidence might very well alter. To such arguments, Stott's investigation provides excellent and critical answers, which Page would almost certainly accept. The latter's picture of the aimless, affectless, and cultureless youth is an accurately observed study of what the sociologist calls asociality. More is already known, through reputable and dispassionate investigation, about these matters than he suggests. That is no criticism of his position. He is the receptive but critical audience to whom social sciences have got to prove their case, and they are likely to derive a good deal of benefit in doing so. If the pikestaff is less plain than it seems, we must demonstrate it in intelligible and convincing terms.

AT the close of the Third World Health Assembly, in Geneva on May 27, Rajkumari Amrit Kaur (India), the president, spoke of the Assembly's "heart-rending" task in cutting out necessary programmes, because of lack of money. W.H.O., she said, should be made better known to the peoples of each nation, for "it is on the peoples' pennies rather than on governmental donations that 'we will thrive.'"

BRITISH PSYCHOLOGICAL SOCIETY

Teaching of Psychology

THE medical section of the British Psychological Society met in London on May 24, under the chairmanship of Dr. H. V. DICKS, to discuss the Teaching of Psychology to Medical Students.

Dr. A. E. CLARK-KENNEDY, speaking as a general physician and dean of the London Hospital Medical School, said that this subject raised the whole question of how medicine should be taught to undergraduate students. It was useless to go on tinkering with the present system; rather, it was time to face complete reconstruction.

The object of the preclinical training was to give the student an idea of the nature of the normal, or (as Dr. Clark-Kennedy preferred to say) the average, man or woman. But how often did it succeed? The ordinary student, befuddled with anatomical fact and overwhelmed by physiological detail, hypnotised by the bogy of an examination which he must pass before he could start work in the wards, might gain a fair idea of the human body as a physicochemical machine, but he usually missed the fundamental concept of it as the product of the plan laid down at its conception and the environment in which it had developed. Moreover, the mind seemed to be omitted altogether from preclinical teaching.

> "We must teach, I think, that the development of the body conditions the development of the mind under the stimulus of education and experience, and that the development of the mind in this way to some extent affects the future development and maintenance of the body on which it depends. True that the *psychosomatic nature of mankind* may be difficult to understand, but is it more difficult than many of the physicochemical concepts which the student is asked to swallow? I doubt it. It is certainly much more important. It should be in his mind from the beginning."

Dr. Clark-Kennedy did not think it would ever be possible, under the existing system, to bridge the gap between the preclinical and clinical subjects by introductory courses or other devices of that kind. The preclinical system—in historical perspective, recent—was already out of date. It was right that the student should learn anatomy and dissect the whole body. He must also know his physiology, though some of the detail now taught could be cut out and the student could manage with less chemistry. But it was wrong that the student should spend his first three years, as at present, ignoring the mind. Moreover, though medicine must draw freely on science, why pretend that it could ever be a branch of applied science like mechanical engineering or commercial chemistry? The unbalanced scientific training provided by the universities was inadequate for a man destined to spend his life in medicine.

Propounding what he called "a most outrageous heresy," Dr. Clark-Kennedy said he was convinced that preclinical and clinical subjects should be taught together. The student should start to work in the wards a little in his first preclinical year, and the proportion of his time spent in the wards should then be progressively increased, while that spent in the laboratory should be correspondingly reduced. But the student should still do some laboratory work in his last clinical year. It would be said that this practice was followed in France, where it did not work; but it was logically right and must be made to work. If at 18 the student was old enough to go into battle, he was old enough to go into the wards.

> "I shall be told that you *cannot* teach any clinical medicine until a student has studied anatomy and physiology. Nonsense! I would like my students in the wards before they have been taught any anatomy or physiology. I see no difficulty in teaching them about mind and body, pain and fever, pulse and temperature, heredity and environment, fear and anxiety, repressions and instinct. Moreover, if they were taught medicine and science simultaneously, how much more exciting would their anatomy and physiology become."

Administrative difficulties must be overcome. At present students were crowded in a relatively small number of hospitals; the field of medical education could be spread much wider.

Psychology was learnt by contact with human nature and mankind; yet during his first three years the medical student led a life more divorced from the humanities and human nature than any other student's. The teaching of psychological medicine to the undergraduate student should be carried out, as far as possible, by general physicians and psychologists grounded in organic disease. The trouble was that the general physician was often content with dividing his cases into organic and functional, disclaiming any particular responsibility for the latter. "In consequence the student gains the idea that 'to be functional' is something peculiar, neither somatic nor psychic, merely discreditable. In fact, through the misuse of the word 'functional,' which has taken on a slang meaning, the whole picture of disease is bedeviled in the student's mind." But Dr. Clark-Kennedy thought this position would slowly change, as it had in the case of physiology.

Many students and doctors had a natural dislike of inquiring into the intimate affairs of other people's lives, while others lacked the tact required. Moreover, the type of mind which would make a good scientist or surgeon, or even a good physician where an organic problem was concerned, might be peculiarly unsuccessful at this aspect of medical practice; and this deficiency could only be remedied to a limited extent. At present there was too much concentration on inpatients, where the problem was usually one of diagnosis and treatment of an organic condition, and too little on outpatients, who provided a cross-section of disease with which the general practitioner had to deal. This aspect of medicine could only be taught in the outpatient department; but the teaching of psychological medicine would always be difficult. The key to both the teaching of psychology and the satisfactory organisation of the student's education lay in the reintegration of medicine. "We must break down the artificial distinctions which we ourselves have set up between health and ill health, body and mind, heredity and environment by teaching the preclinical and clinical subjects simultaneously."

STUDENT AND TEACHER

Prof. D. R. MACCALMAN (Leeds) remarked that while most medical schools gave some prominence to the teaching of psychiatry, some had not so far thought it necessary or desirable to include normal psychology in the curriculum. Yet if physiology was the logical predecessor to pathology, surely psychology was a necessary foundation to the teaching of psychopathology. He believed that any subject could be fitted into the medical course, provided it was shown to be important enough. Here the psychologists had themselves to blame. They should show that psychology was a scientific discipline, concerned with the measurement and comparison of measurable and comparable quantities.

In the preclinical years students relied greatly on intelligence and memory, for such subjects as physics and anatomy demanded little else. From the very beginning of their clinical studies they would be faced with people who were far from being rational in their behaviour; and to understand human nature, they needed qualities of character other than reason and intellect. In addition to open disparagement of psychology and psychiatry, the student came under the influence of theories and methods which underlay the hospital management of patients and the general philosophy of medical practice. As Colman had pointed out, patients were given advice, suggestions, encouragement, reassurance, or anything else which established the physician as an authoritative father-figure and the patient as the obedient and compliant child-suppliant. The problem with this method of psychotherapy was not its use by psychiatrists, who only saw the psychiatric patients, but its distressingly wide application by the general body of physicians.

The teaching of psychotherapy, Professor MacCalman declared, should begin in the first year at the medical school. From the very beginning the medical student should be taught that he himself was a human being, the success of whose work would largely depend on his reactions to the attitudes and emotional needs of his patients. The teacher must adapt himself to the student's immaturity. Much more use should be made of the tutorial system, and the teaching of small groups. In medical schools there was too much of what Adolf Meyer called "the adoration of personalities," and too little recognition of negative transference. Too many teachers played the authoritative father-figure, and demanded of the student the rôle of child-suppliant. Instead, the student required a teacher who would allow him to talk about his difficulties in learning, who would tolerate his ignorance, and who would correct his mistakes without malice or sarcasm. The teaching of psychology to medical students was the first step towards providing them with a knowledge of themselves and their fellow men which would illuminate and enrich their clinical skill as doctors.

THE STUDENT'S INTERESTS

Dr. A. D. **Harris**, of the Medical Research Council's applied psychology research unit, described the findings from the records of medical students who consented to be interviewed in an investigation into selection methods. Among 400 such students, the number of intending psychologists or psychiatrists was 44 (11%)—a proportion exceeded only by those who had not yet decided what they intended to do after qualifying (32%), and by those who wanted to be surgeons (24%). They were slightly more numerous than the general practitioners, and considerably more numerous than the adherents of general medicine or any other specialty. These figures agreed approximately with those for a provincial medical school given by a peripatetic correspondent in The Lancet.[1] Surgery held pride of place probably because of its obvious power to stimulate the imagination; the same factor might be recognised in the growing interest in psychology.

Of the 44 who wanted to be psychologists, 31 were interested in abnormal psychology, psychiatry, psychoanalysis, or psychological medicine; and 13 in general, experimental, or social psychology. Their reading-matter ranged from a systematic exploration of the *Encyclopædia Britannica* to an interest in the *Greyhound News*. An analysis of the authors read by the 22 ($5^1/_2$% of the total) who had read books on psychology showed that though an interest in psychology was fairly common among medical students, it was not always directed into the most profitable channels. On the basis of the first medical examination and a standard intelligence test, the students who wanted to specialise in psychology were not found to differ significantly from their fellows; but this group contained more of the highly intelligent and of the stupider students than would have been expected in a random sample. Interview records did not suggest that they were distinguishable from other medical students.

These considerations cast doubt on two objections sometimes raised to the teaching of psychology to medical students: (1) that such teaching was unfavourably received, and (2) that it might be unsettling or even dangerous to their mental stability. If students' preferences were to be considered, psychology had as good a claim as any other subject, except surgery, in the clinical period—and a far better claim than, say, botany in the preclinical years. As to the second objection, it would be as reasonable to argue that because some students were unduly worried about their physical health, there should be less instruction concerning the human body and its ailments.

Dr. Harris thought that the teaching of psychology to medical students should have a practical bias; the student should realise that the reasons for recognising a psychiatric emergency were of exactly the same kind as the reasons for recognising acute otitis media or a perforated appendix. What was taught should be verifiable, and so far as possible generally agreed. The application of these criteria might greatly reduce the amount which medical students could beneficially be taught. "If so," Dr. Harris concluded, "it seems to me that, whatever the state of demand, psychologists should be chary of accepting a more prominent rôle in medical teaching. It would be a mistake to suggest that psychologists are standing outside the medical schools waiting for an opportunity to make available a large body of fundamental teaching, until we are convinced that this is really the case."

Dr. **Emanuel Miller** said that in an investigation among third-year and fourth-year students he had obtained rather different results to Dr. Harris's. Asked whether they thought that psychology ought to be included in the medical curriculum, 35% answered No. Of those who answered Yes, 88% wanted the course in the preclinical years. He had found that a number had written "no" in answer to this question larger than they had written it in answer to other questions; some had written "no, no" and some had even written "never, never." This suggested that the negative replies were not entirely due to opposition to the idea of adding another subject to an overcrowded curriculum. Only 7% of the students had read any books of psychology.

A CONTINUING COURSE

Dr. Miller suggested that psychology could not be introduced into the medical curriculum by a mechanical addition of new subject-matter which lay outside an established tradition. A favourable mental climate could be produced in medical schools and hospitals only by the coöperation of physician and psychiatrist; both must make sacrifices for a common end—making medicine a branch of scientific humanism. The attitude of *non est vivere sed valere vita* could only be grounded in psychology. In a large measure psychology might prove to the young doctor more basically important than psychiatry, because he would be confronted by at least hypothetically normal patients. For all practical purposes the mental processes, outside of neurosis and psychosis, were within a normal statistical range. Throughout, the accent should be on the total person, so that when the student arrived at mental disorders he would see them as disturbances of persons and not as diseases. Nor should there be failure to teach the lesson of psychological constitution rooted in inheritance and blossoming in psychological types.

Though few students had much knowledge of life beyond the innuendoes of the Light Programme, an appreciable number knew something of social relations; and the elements of social psychology could and should be imparted to them, so that when they entered the wards and the outpatient department they would see sick people as social units. Since the mass teaching of psychology had certain grave disadvantages, students who attended lectures might be invited to special study groups.

Psychology should be taught with no other purpose than to illustrate its relevance in the departments of medicine which needed its fertilising influence; and it should be conveyed with a view to the student's being examined at the end of the period of instruction. If given in one block of lectures, the instruction would appear isolated from the body of medicine. The rudiments could be introduced in the physiology course; by the time students had completed their anatomy and physiology courses, they would have had perhaps five lectures, which would provide them with a basic vocabulary and basic concepts. When he entered the wards, the student could be supplied with lectures from which he would apply to special subjects the knowledge already gained. Problems of personality structure, interpersonal relations, and social psychology could be discussed at various periods of the clinical course, so that they were relevant to the various medical subjects. In pædiatrics the psychologist would give a short course on child development; and the gynæcologist might spare a few lectures for psychology of sexual development. The student would come to realise that psychology no more left the life of the hospital than did the expert on morbid anatomy and the applied physiologist. Above all, psychology should be taught with an eye to scientific method.

---

[1] *Lancet*, 1949, i, 796.

Preferably the teaching should be done by a physician in psychiatry who knew his colleagues' prejudices and apprehensions, and understood the climate of the hospital and the mentality of the "normal patient." But some aspects of psychiatry, particularly scientific method, would best be conveyed by a trained general psychologist.

HARVARD AND MELBOURNE

Dr. D. W. **McElwain** (Melbourne) supported two points emphasised by the Harvard Commission on the Place of Psychology in an Ideal University.

The first was that all teaching of psychology in a university should be centralised. Should the teaching of all applied or specialised courses in psychology be conducted from the school of psychology which was primarily responsible for the training of psychologists, or was there a valid case for the present practice whereby special courses were conducted in the professional schools by teachers within these schools, who commonly were not psychologists? This issue arose, not only with the teaching of psychology in medical schools, but also with educational psychology in teacher-training and with industrial psychology in management courses. The teacher identified with a particular professional school was often cut off from the main stream of the subject which he presented to his students. The Harvard report recommended that "every psychologist in the university should be attached to the psychology department"; but, accepting this principle, was the teacher of psychopathology—a psychiatrist usually—a psychologist within this meaning? In the University of Melbourne the teaching of psychopathology was a function of the psychology department. The senior lecturer in psychopathology was qualified both in psychiatry and psychology. He was a full-time officer of the psychology department, responsible for the teaching of this subject, not only for the medical school, but also for the psychology department and for the department of social studies, which trained various social workers. This arrangement had been effective.

The second point emphasised in the Harvard recommendations was that any course in applied or specialised psychology should be preceded by a course in general psychology. The particular schools of medicine, theology, and the rest usually asked for short intensive courses of lectures which would make clear the psychological theory of the problems of the school concerned. Such courses were worse than a waste of time. The general course which preceded any special course must be adequate in level attained and in breadth. This was not possible without an introduction to the methods of psychological inquiry—which meant a suitable amount of practical work. The general course should have about 150–200 "student-contact" hours.

Dr. McElwain then outlined a scheme for psychological teaching consisting of the following courses:

Course	*No. of hours*
(*a*) General psychology I (introductory)	150
(*b*) General psychology II (a more advanced theoretical course)	250
(c) Psychopathology I (introductory)	200
(*d*) Psychopathology II (advanced)	250

The medical undergraduate would take course (*a*) in one of his preclinical years and course (*c*) in one of his clinical years. This would be supplemented with training in elementary psychotherapy in the clinical schools—which, as a training in therapeutics, would be no direct concern of the psychology department. Students for the diploma of psychological medicine would take courses (*b*) and (*d*), together with their advanced work in psychiatry, neurology, &c. The psychology student would take courses (*a*), (*b*), and (*d*) as components of his honours degree; and the psychiatric social worker would also have these courses.

In the University of Melbourne this scheme was almost fulfilled. The psychology department conducted for medical undergraduates courses in general and abnormal psychology; but both were in the clinical years and were at present shorter than was desirable. The D.P.M. candidates were required to take courses (*a*) and (*d*), and most also took course (*b*) (so completing a B.SC. degree); and the social workers completed a full B.A. degree (with psychology as a major subject) as a prerequisite to the granting of diploma status. The psychologist, psychiatrist, and psychiatric social worker attended courses together; and in the general psychology course the medical student was also brought into contact with the students in orthoptics and tutor nurses. "We hope that these people who are to work together later will not only know a fair amount about each other's work, but will also know each other personally, having trained in the same classes." Dr. McElwain added that the attitude of clinical students towards psychology was eased by their having been "dosed" with general psychology, and that an increasing number of students were taking an honours degree in psychology and physiology before taking the course in medicine.

FURTHER OPINIONS

Dr. W. R. **Bion** said that he thought from the point of view of the general practitioner it would be helpful if he were taught to be suspicious whenever a patient or his family seemed to be denying him the minimum conditions necessary for adequate treatment of his case. The general practitioner, considering his case in this kind of way, would then be led to consider whether he ought to call in a psychiatrist or not. Such an approach in a teaching hospital would cover practically the whole of psychiatry.

Prof. H. E. **Field** (New Zealand) thought the key defect was that psychological phenomena were regarded as less real than physical ones. Associated was the notion that common sense was enough. On that ground there was a good case for the careful introduction of psychology in the early stages of the medical student's training. Furthermore, the introduction of psychology would not only affect his attitude to psychology but would give him a healthy scepticism in regard to science.

Dr. **Joyce Partridge** said that she had been told by men and women students that they were most anxious to be taught about functional cases and did not find they were so taught. Their complaint was not against the general physicians but against the psychiatrists who had beds in the hospitals and who sent out cases labelled as being "only functional."

Dr. **John Rickman** was doubtful whether medical students were the right people among whom to carry out "consumer surveys" on the demand for psychological training; the proper time to inquire into the adequacy of the medical course was in the first few years after the young doctor had gone into practice. When the apprenticeship system was in vogue, the student went into the homes of the patients, but that system did not provide sufficient scientific basis. Dr. Rickman believed, however, that it was only very partly true that doctors learned best in hospitals. If man was to be studied in his social environment, that study could not be carried out satisfactorily when he had been removed to hospital. The hospital was the best place to study "parts of the machine" but not "the whole person."

The CHAIRMAN, closing the discussion, recalled the Collings report. He had a strong feeling that it reflected some sort of morale problem among general practitioners, arising from their inadequate training for the psychological aspects of their daily work. What was possible in Australia—as described by Dr. McElwain—should be possible in this country. He thought that the approach should be first from the clinical side in the wards of a general hospital. Students should be taken to the bedside to hear a skilled psychologist taking life-histories: they would there see resistances and tensions arising and being dealt with. Early in the clinical training it should be possible to introduce the psychiatric social worker; if she was introduced at a later stage the idea was pooh-poohed on the grounds that she was a laywoman. Medical teachers should be taught psychology lest the students, outstripping them, became frustrated, and so, in general practice, found themselves having more Collings reports written about them.

GENERAL MEDICAL COUNCIL

SESSION MAY 23–27

(Concluded from p. 1047)

More Disciplinary Cases

Alummootil Paul Abraham, registered as of 265, Eccles New Road, Salford, M.B. Madras (1944), was charged with having canvassed patients of Dr. W. G. R. Wilson in a practice at Salford to which Dr. Wilson had been appointed in November, 1948, in succession to the late Dr. L. D. Stephen. In particular Dr. Abraham was charged with having canvassed Mrs. J. E. Shepherd, with endeavouring to procure Mr. James Johnson to put his medical card and the medical cards of his family into his possession, and similarly in respect of Mrs. Lavinia Spruce, Mrs. Lucy Heywood, Mr. Harold Hurst, Mrs. Emily Glencross, Mrs. May Redmond, and Mrs. Emma Byrne, and with canvassing Mr. James Dixon and Mrs. Eva Burrow.

Mr. N. Leigh Taylor, of Messrs. Hempsons, solicitors, appeared for the complainants, the Medical Defence Union, and Mr. B. H. Gerrard, instructed by Goulty and Goodfellow, solicitors, appeared for Dr. Abraham.

Mr. Taylor said that Dr. Abraham had acted as locum tenens for Dr. Stephen in a working-class practice in Salford. When Dr. Stephen died, Dr. Wilson applied successfully for the vacancy. Dr. Abraham also applied but failed; he appealed and again failed. All the people in the charge had been patients of Dr. Stephen. Dr. Abraham ceased to be locum tenens in 1949, and in that year set up in practice on his own, about three-quarters of a mile from the surgery formerly occupied by Dr. Stephen and now occupied by Dr. Wilson.

Mr. Taylor said that he would produce witnesses to testify on four of the charges, and Dr. Wilson would explain why the other persons who had made statutory declarations were not present. It was ruled that at this stage Mr. Taylor should not refer to the cases in respect of which there were only statutory declarations.

Outlining the cases in which there was supporting oral evidence, Mr. Taylor said that Mr. Johnson would say that Dr. Abraham paid various calls to inquire how the family were getting on, and later told Mr. Johnson that he was setting up in practice and expected their cards. Dr. Abraham, in his reply, referred to a particular visit to Mr. Johnson's house and said the reason was that Mr. Johnson's son-in-law had called him; Mr. Johnson would say the son-in-law had called Dr. Wilson. Dr. Abraham said that the other visits were in connection with watch-mending.

Dr. Abraham, continued Mr. Taylor, had met Mrs. Glencross when she was shopping, offered her a lift, said he was starting in practice, and asked her for her cards. Dr. Abraham denied offering her a lift, said he had never been to her house since he was a locum tenens, and agreed that he saw her once in the street, when she asked him what he was doing, but again he denied canvassing.

Mr. Dixon had been told by Dr. Abraham that he was getting new premises and would let him know when he got them. In December, 1948, Dr. Abraham called on him and gave him a list of names of householders and asked him to sign in the appropriate place and get the others to do the same; Dr. Abraham told Mr. Dixon another doctor was trying to get the practice and he wanted as many names as he could to send to the council. The vacancy, commented Mr. Taylor, was not advertised until after that time. Dr. Abraham denied ever attempting to get Mr. Dixon to transfer to his list.

Mrs. Eva Burrow was a patient of Dr. Stephen's who had been attended by Dr. Abraham. Dr. Abraham had stopped her in the street and told her he was setting up in practice in Eccles New Road and would be pleased to see her or her children at any time. Dr. Abraham stated that there was an occasion when he was standing outside his surgery when Mrs. Burrow asked him if it was his surgery, but he did not canvass.

Dr. Wilson, examined by Mr. Taylor, told how he had come into Dr. Stephen's practice and had not seen Dr. Abraham when he took over. Dr. Wilson gave the medical and other reasons why the remainder of the persons who had made statutory declarations which were the subject of charges were unable to be present.

Cross-examined, Dr. Wilson agreed that Salford was a highly populated area with many doctors and was not an area closed to doctors. He denied that the reason he did not go to see Dr. Abraham was because Dr. Abraham was coloured. Dr. Wilson said he asked Violet Bartlett whether Dr. Abraham had canvassed her. Mr. Gerrard: "Did you say: 'I'm going to have Dr. Abraham sent back to India where he belongs?'" Witness: "Rubbish." He did not say to Mary Tench that there should be a white doctor for white men and black for black. Dr. Wilson further denied that he told Margaret Rowbotham that he would "get this nigger black run out" or that he had better qualifications than Dr. Abraham. He agreed that a Mrs. Dodd, who phoned him, was very angry with him and reported him to the secretary of the Salford Executive Council. Witness agreed that over 99% of the people in Salford had registered under the National Health Service. Mr. Gerrard: "Did you lose one of the cases referred to in the counts?" Dr. Wilson: "No."

In re-examination, Mr. Taylor read a letter from the chairman of the local medical committee sent to doctors in the area stating that, as membership of the scheme in the area was about 100%, an increase in the numbers of patients on the list of one doctor could only come from another doctor. The letter went on to refer to the traffic in patients having developed to an enormous extent and warned against canvassing.

Evidence was then given by four of the persons mentioned in the charge. Mr. James Johnson said that he had been attended by Dr. Abraham when Dr. Abraham was acting as locum. After Dr. Wilson had arrived, Dr. Abraham saw witness at his house. He called when witness's daughter was ill, when Dr. Wilson had been asked to come. "I asked him what he was going to do now," said Mr. Johnson; "he shrugged his shoulders." Witness's son had done watch-repairing for Dr. Abraham.

Mrs. Emily Glencross said her husband and child had been treated by Dr. Abraham when he was locum. When Dr. Wilson took over they were automatically transferred to his list. She met Dr. Abraham when out shopping about March, when he offered her a lift. He said he was going to open a place in Eccles New Road. A week or so after, Dr. Abraham called at the house and asked if he could have their cards. She told him she had seen Dr. Wilson and was satisfied, and he went out.

Mrs. Eva Burrow said Dr. Abraham had looked after her as a locum. In January or February, 1949, he met her in the road near his new surgery, which was being prepared, and told her he was opening the premises soon and would be pleased to see her or the children any time they liked to call.

Mr. James Dixon gave evidence of Dr. Abraham calling on him and his housekeeper. Cross-examined, witness said Dr. Abraham did not ask for their cards.

At the conclusion of this evidence, Mr. Taylor asked permission to read the statutory declarations in support of the other charges. Mr. Gerrard submitted that the council could admit statutory declarations at their discretion, provided the evidence justified it; he suggested that there had not been a case from the four witnesses who had been heard to warrant the inclusion of the statutory declarations. After deliberation in camera, the president announced that the council had decided not to admit the statutory declarations.

Mr. Gorrard then submitted that there was no case to answer. Of the four witnesses called, Mr. Dixon, Mr. Johnson, and Mrs. Burrow had said nothing detrimental, and Mrs. Glencross, who had made an allegation, when asked if she had seen Dr. Abraham since the day she had seen him in the street, said she had not.

Mr. Taylor said that Mrs. Glencross's evidence alone was sufficient to convict if the council so wished.

After consideration in camera, the President announced that the council had found the facts alleged against Dr. Abraham not proved to their satisfaction.

ADULTERY ADMITTED

Eric Allan Peter Sutherland-Rawlings, registered as of 1, Burwood Place, London, W.2, M.R.C.S. (1928), appeared before the council on the following charge of infamous conduct in a professional respect:

(1) You committed adultery with Gwyneth Lyons, of which adultery you were found guilty by the decree and Admiralty Division . . . in the case of Sutherland-Rawlings, in which you were th stood in professional relationship with the at all material times.

Mr. Gerald Howard, K.C., M.P., and Mr. Magregor, instructed by the council's solicitors, stated the case, and Mr. C. R. Havers, K.C., and Mr. Ormerod, instructed by Brown, Baker, and Baker, appeared for Dr. Sutherland-Rawlings. The fact that the alleged adultery took place was not disputed.

Mr. Howard said that a sheet from Dr. Sutherland-Rawlings's account book would be produced which was headed "Miss G. Lyons, consultation, 1 gn."; that was settled in March, 1948, and it appeared that from Dec. 31, 1947, Miss Lyons was a patient. In 1949 Mrs. Sutherland-Rawlings made a discovery as a result of which she was granted a decree nisi, the doctor filing no answer; the decree was made absolute on Dec. 17, 1949. Documents indicated that for months Dr. Sutherland-Rawlings was giving treatment to Miss Lyons. These included a copy of a laboratory report headed "Miss G. Lyons," letters from another doctor regarding Miss Lyons, and a letter from a specialist.

Mrs. Jane Sutherland-Rawlings said that she assisted her former husband in his practice, doing the secretarial work and keeping the books. She identified the page from the ledger and copies of the letters. Cross-examined, she said she took the page from the ledger because she already knew that Miss Lyons was a patient and she wanted it in black and white. She agreed that she continued opening her husband's correspondence after her solicitors had given an assurance that she would not do so. She denied that she wanted to ruin her husband. Mrs. Sutherland-Rawlings agreed that her husband kept a "surgery book" and that she copied the entries from this to the "day book," from which the ledger was made up and the accounts sent out by her.

Miss Dorothy Lyons, called by Mr. Havers, said she was the sister of Miss Gwyneth Lyons. She and her sister first met the doctor at the house of a friend, and Dr. Sutherland-Rawlings subsequently frequently visited their flat. At the end of December, 1947, her sister thought she was pregnant and went to see Dr. Sutherland-Rawlings; her sister did have a doctor of her own. Mr. Howard: "She was consulting him (Sutherland-Rawlings) as a doctor in order to see him at all?"—"I suppose so, yes."

Dr. Sutherland-Rawlings in the witness-box said that his late wife had looked after the business side of his practice. He met Miss Lyons at a party, where he was introduced to her and her sister. Afterwards he paid visits to their flat and intimacy took place between him and Miss Gwyneth Lyons on several occasions in 1947. At the beginning of December, 1947, they agreed not to see each other for a trial period of a month, but on Dec. 31 she came to his surgery. He did not know she was coming; he did not want her to come; he had not been told she had an appointment. He pointed out to her that it was very unwise of her to come to the surgery and it put him in a dilemma. She insisted on making the subsequent visits. He made the entry of this and subsequent visits in the surgery book because the visit was entered by the receptionist and had to be accounted for in the other book and “feed up.” Miss Lyons insisted that she should have a test and he gave her a container to obtain the specimen. Miss Lyons had never come to his surgery before Dec. 31, 1947, or after Feb. 2, 1948, and he never rendered her professional service. It was never his intention that she should pay; he paid the bill himself. After he made a settlement with his wife he went to live with Miss Lyons as man and wife, and it was then that she said she had something wrong with her knee and he told her she should see the specialist, and he told her of the other doctor whom she went to see. Cross-examined, Dr. Sutherland-Rawlings said he did not send Miss Lyons to another doctor when she came to see him, because he did not want to bring the matter out. He did not give her any advice as a doctor. Asked by Mr. Howard whether he would have done any more than he did had Miss Lyons been a complete stranger, Dr. Sutherland-Rawlings replied that he would have examined her.

Mrs. Gwyneth Sutherland-Rawlings, formerly Miss Lyons, corroborated the doctor's evidence. She said that a friend at work, who suggested it, made the appointment for her to see Dr. Sutherland-Rawlings on Dec. 31.

Mr. Howard, cross-examining: "Was one of the reasons for going to Dr. Sutherland-Rawlings to ask him as a doctor whether you were pregnant?"—"No." "Did you ever ask Dr. Sutherland-Rawlings as a doctor whether he could find out if you were pregnant?"—"No."

"What you are really saying is that the real object of your visits was to see him as your lover, not as a doctor?"—"Yes."

Evidence was also given by other witnesses.

At the end of the proceedings in the case, the President announced that the council had found that the facts alleged against Dr. Sutherland-Rawlings in head 2 of the charge had not been proved to their satisfaction; the case was therefore ended.

ADULTERY DISPUTED

Reginald Frank Stubbs, registered as of Sannomiya, Hale Road, Hale, Cheshire, M.B. Manc. (1928), appeared on the charge that:

(1) You committed adultery with Freda Rose Mitchell, a married woman, of which adultery you were found guilty by the decree of the Probate, Divorce, and Admiralty Division . . . in the case of Mitchell v. Mitchell and Stubbs in which you were the co-respondent. (2) You stood in professional relationship with the said Freda Ros Mitchell at all material times."

Dr. Stubbs was represented by Mr. N. Richards, instructed by Messrs. Le Brasseur and Oakley, on behalf of the Medical Protection Society, and Mr. Howard, K.C., M.P., with Mr. R. J. Lowry, instructed by the council's solicitors, appeared to state the case. For Dr. Stubbs it was contended that he did not commit the adultery set out in the charge, and that he did not stand in professional relationship to the woman at all material times.

Mr. Howard said that Mrs. Stubbs had a schoolgirl friend who became Mrs. Mitchell. After these two friends married, the one becoming Mrs. Stubbs, the other Mrs. Mitchell, they lived close together at Hale. It appeared that Dr. Stubbs first saw Mrs. Mitchell professionally in 1936 and from that year he was a frequent visitor to the Mitchells' house. Evidence would be given of his professional attendance on Mrs. Mitchell from 1936 to 1947.

Mr. Howard explained that when divorce proceedings were taken, by Mr. Mitchell, evidence was given by two inquiry agents. The commissioner did not accept their evidence as proof that adultery had taken place at a hotel and dismissed the petition. The Court of Appeal, however, reversed the commissioner's finding and granted a decree nisi, which was made absolute on Aug. 10, 1949. Dr. Stubbs at no time made any defence to the proceedings.

Evidence was given by Mr. J. F. Mitchell. In cross-examination he was asked: "From the start of your marriage your wife was openly visiting Mr. and Mrs. Stubbs?"—"Yes." "Is it right to say that long before he treated her professionally he knew her socially?"—"Yes."

Dr. Stubbs in the witness-box said that he first met Mrs. Mitchell at a party before she was married and before he had married a second time. He treated her for a cut finger in 1936 and for influenza in 1946. He sold his practice in 1948 and left Cheshire on Feb. 22, 1948. Questioned about what happened at a hotel in Richmond, he denied that adultery took place. Mrs. Mitchell and he did not defend the divorce proceedings because it would have brought them back to the intolerable conditions from which they wanted to escape.

Mrs. Freda Rose Stubbs, formerly Mrs. Mitchell, said she first met Dr. Stubbs at a party about 1928; she was not a schoolgirl friend of Mrs. Stubbs. Between 1934 and 1939 she frequently met Dr. and Mrs. Stubbs socially. She corroborated Dr. Stubbs's evidence about the hotel visit and the divorce. Cross-examined, she agreed that in so far as she had a doctor before the war, it was Dr. Stubbs, and similarly after the war.

Mr. Richards in his closing address said it was true the Court of Appeal had granted a decree, but it could do so on circumstantial evidence. The court said that the inference to be drawn from the facts was such that when the suit was not defended it might be inferred that adultery took place. That did not mean that the parties could not come to the council and say that although they did not defend the suit they did not commit adultery. If the council found that the adultery alleged in the first head of the charge was not proved, they were not concerned with the second, but if they found the first count proved, they had to consider whether Dr. Stubbs was in professional relationship at all material times. Mr. Richards submitted that attendance on Mrs. Mitchell as a medical man was purely incidental. This was not a case of a man meeting a woman for the first time because she was a patient. All the way through they continued to meet socially.

After hearing Mr. Howard in reply and deliberating in camera, the president announced that the council had found the facts alleged against Dr. Stubbs in head one of the charge (the adultery in respect of which the divorce was granted) not proved to their satisfaction.

SEXUAL PERVERSION

A practitioner appeared before the council charged with having been convicted of an offence arising from sexual perversion, for which he had been sentenced to twelve months' imprisonment. The case was heard in camera, and at the end the President announced in public that the council had not seen fit to direct the Registrar to erase the practitioner's name from the register.

COÖPERATION BETWEEN HOSPITAL, GENERAL-PRACTITIONER, AND LOCAL-AUTHORITY SERVICES

THE Central Health Services Council has appointed a committee to study means of promoting coöperation between the hospital, general-practitioner, and local authority services. It will consider existing forms of coöperation between (i) regional hospital boards, hospital management committees, and boards of governors; and (ii) local authorities; and (iii) executive councils; and report whether it is possible to formulate any general principles on which coöperation might be promoted between these authorities. The members of the committee are:

F. MESSER, C.B.E.; M.P. (chairman); Sir HENRY COHEN, F.R.C.P. (vice-chairman); Sir ERNEST ROCK CARLING, F.R.C.P.; Sir ALLEN DALEY, F.R.C.P.; F. HALL, C.B.E., M.D; Captain S. H. HAMPSON, M.B.E., M.C., LL.B.; the Hon. ARTHUR HOWARD, C.V.O., M.P.; W. V. HOWELLS, M.B.; K. I. JULIAN, C.B.E.; Prof. HILDA LLOYD, F.R.C.O.G.; R. A. MICKELWRIGHT, F.H.A.; Sir CECIL OAKES, C.B.E.; Councillor WILLIAM ONIONS; Prof. R. H. PARRY, F.R.C.P.; W. G. PATTERSON, M.D.; E. W. SCORER, O.B.E.; A. TALBOT ROGERS, M.B.; Alderman W. E. YORKE, C.B.E.

The joint secretaries are Mr. E. J. S. Clarke and Mr. J. T. Woodlock, of the Ministry of Health.

Reconstruction

JOINT CONSULTATION IN HOSPITALS

TOM E. DALTON

THE joint consultative committees which are now to be set up in hospitals with the approval of the General Whitley Council and of the Ministry of Health will make further demands on those concerned with the efficient running of hospitals.

In industry joint consultative committees have not always achieved their purpose; and even in those branches where some measure of success has been recorded they have sometimes produced strained relations between workers and management. The setting up of such a committee in a hospital will not automatically produce harmonious relations. Furthermore, joint consultation is not an end in itself, but merely a means whereby workers can get a better grasp of the difficulties of management, and the management a better grasp of the contribution that workers can make.

Hospital administrators can learn some useful lessons from industry. In the past thirty years many erstwhile theories have been discarded. Thus, economic considerations are no longer regarded as the principal activating force; and tradition has proved a stronger factor than reason in influencing the way a worker does his job. Moreover, it has been increasingly recognised that workers are—very naturally—sensitive about anything that impinges on their self-respect. They desire an outlet for their grievances, and a chance to put forward their ideas and theories and to ask the why and wherefore of processes and policies determined by their managers. Joint consultation can help to satisfy these needs, and to make workers aware that they are an important part of the concern.

In 1918 the Ministry of Labour—well in advance of its time—published the following list of functions ("not meant to be exhaustive") suggested as suitable for discussion by works committees: (1) issue and revision of works rules; (2) questions of discipline and conduct as between management and work-people: (3) terms of engagement of work-people; (4) technical library, and lectures on the technical and social aspects of the industry; (5) the training of apprentices; and (6) suggestions for improving the methods and organisation of works, and the testing of suggestions.

With time and experience, the list of functions has been expanded. In industry, however, the traditional distrust between employed and employer remains; there is little enough common ground. The worker still regards the making of profit as a form of exploitation of his services; so there is conflict on policy. In hospitals, on the other hand, there is a very powerful emotional impulse which, if properly used, can provide common ground; the alleviation of suffering arouses in most minds a sympathy that can transcend all other motives.

PROPOSED ORGANISATION

The committees now to be set up will not discuss rates of pay or total hours of work. Special machinery exists for dealing with such matters; and to permit discussion of them would be to undermine the authority of such bodies as the joint industrial councils and the Whitley councils.

The committee's functions are to be as follows:

1. To promote the closest coöperation and provide a recognised means of consultation between the management committee or board of governors, its senior officers, and staff.
2. To give the staffs a wider interest in, and a greater responsibility for, the conditions under which their work is performed; to give the maximum assistance in promoting the welfare of the patients and efficient administration in the hospitals controlled by the committee or board; to make suggestions for the improvement of the general arrangements for the comfort of the staff, their recreation, entertainment and dietary.
3. To prevent friction and misunderstanding.
4. Subject to the proviso that no recommendations of the *hospital staffs committee shall conflict with, or override,* any decision of the general council or the appropriate functional council, to deal with such matters as: *(a)* the distribution of working hours; *(b)* holiday arrangements; and *(c)* questions of physical welfare (cloakroom arrangements, heating *ventilation, &c.).*
5. To consider any hospital rules affecting staff, apart from any that may be prescribed nationally or regionally.

Members are to be elected from the following grades of staff: administrative and clerical; nursing and midwifery; technical and professional other than nurses and midwives; domestic, farm, and garden; and artisan.

n a circular to hospital authorities (R.H.B. [50] 47) Ministry of Health declares that "it is contemplated t consultative committees will be set up in all hospitals ept where the small number of staff makes such a nmittee inappropriate." Committees, it is pointed out, uld be set up for individual hospitals rather than ups, since the whole purpose of the consultative chinery is to enable local problems to be discussed. en in a small hospital the management committee ould not oppose the setting up of a committee if the ff clearly desires its establishment; and where a mmittee is not appropriate or desired, arrangements ould be made for informal consultation between anagement and staff on matters which would be vered by a committee. There is no need, adds the cular, for the two sides of the committee to be evenly lanced in numbers; "and, indeed, it is perhaps eferable that the management side representatives ould be fewer in number than the representatives on e staff side." Since the committee's recommendations e decided by agreement between the two sides—and ot by a vote of the whole committee—this does not ffect decisions.

THE CHAIRMAN

On the chairman will depend the ability of each of these committees to develop a common purpose through steady development of joint responsibility and attention to sound administrative principles. He must be a Solomon in wisdom and a Job in patience. In particular, he must be prepared to recognise that delegates from the staff side have a better grasp of hospital problems than may be supposed. He must be able to grasp a point being made by a hesitant, and perhaps incoherent, delegate, and to present it in a form understandable to all. With a mediocre chairman such a delegate may get no encouragement, or no chance to make his contribution; and the committee will be thereby the poorer.

Joint consultation has nothing to do with workers' control, with which it is often confused. In any project there can be only one management; if the workers are in control, then they are the management, and are faced with the same problem as their predecessors—that of obtaining the willing coöperation of everyone in their organisation. It is this willing coöperation that joint consultation seeks to achieve.

Medicine and the Law

The Nurses' Elections and the Returning Officer

THE difficulty which arose lately over the election to he General Nursing Council for England and Wales aises questions of the powers and responsibilities of a returning officer. It will be recalled that, under the 1949 Act, the new constitution of the Council is to include 14 elected members who will respectively represent each of the 14 areas into which the Minister has for this purpose divided the country;

> "and each of these nurses shall, on the date of the election, be engaged in the area for which he '[the Interpretation Act, of course, provides that "he" includes "she"]' is elected, in nursing or in other work for which the employment of a registered nurse is requisite or for which a registered nurse is commonly employed."

So runs the statute, and presumably no rules purporting to be made under the statute could vary the words "engaged in the area" by narrowing their sense to "exclusively engaged in the area"; nor could a returning officer take it upon himself as a matter of administrative practice arbitrarily to insert an important adverb into the text of the statute so as to alter the meaning. Certain nominations, however, for election to the General Nursing Council were rejected by the returning officer for the ostensible reason that the candidates were not exclusively "engaged in the area" concerned. The Ministry of Health was invited to give an authoritative interpretation of the material phrase; *it declined* on the plea that it is for the courts and not for the Minister to give a ruling of this kind. How the point should be referred to the courts, or who will pay for the privilege of clarifying the law, the Ministry's reply did *not* explain. Meanwhile it became known that in certain other cases seemingly parallel to those of the rejected candidates no disqualification had been pronounced.

Some analogy may be found in the position of returning officers at parliamentary or local-government elections. In a Berwick-on-Tweed case in 1946 (Watson *v.* Ayton) the mayor, acting as returning officer at a local-government election, rejected as invalid the nomination of a candidate described as a "schoolmaster." The mayor assumed that the schoolmaster was the paid employee of the Northumberland county council and therefore, under section 59 (2) of the Local Government Act, 1933, *ineligible.* The court held that the mayor had no sure evidence of the candidate's official activities and could not decide the issue of disqualification from such information as appeared on the face of the nomination paper. The Committee on Electoral Law Reform, many of whose recommendations were carried out in the Representation of the People Act, 1948 (now largely consolidated in the Act of 1949) expressed the view that the ruling in the Berwick-on-Tweed case should be incorporated in the statute law. Accordingly Rule 9 (2) of the Third Schedule to the Act of 1948, reproduced as Rule 13 (2) of the Parliamentary Elections Rules in the Second Schedule to the Act of 1949 and there declared to be applicable to local-government elections, states that the returning officer is entitled to hold a nomination paper invalid *only* on one of the two following grounds:

> "(*a*) that the particulars of the candidate or the persons subscribing the paper are not as required by law, and
> "(*b*) that the paper is not subscribed as so required."

The nomination paper at a parliamentary election must, under the statute, state the full names, place of residence, and description of the candidate; the description must not refer to his political activities (i.e., he must not be described, for instance, as "the Labour candidate") and, if it is unduly long, the returning officer may (in consultation, if possible, with the candidate, his agent or sponsors) shorten it or substitute another. The material fact is that the returning officer is concerned only with the nomination paper, not with the nomination as distinct from the nomination paper. He cannot enter into the question of the candidate's qualification. The recent legislation appears to be reconcilable with the judgment of Mr. Justice Wright in Harford *v.* Lynskey in 1899: "If the nomination paper is, on the face of it, a mere abuse of the right of nomination or an obvious unreality, as for instance if it purported to nominate . . . a deceased sovereign, there can be no doubt that it ought to be rejected and no petition could be maintained in respect of its rejection."

If these principles are applicable to the General Nursing Council elections, the recent action of the returning officer seems questionable, though no-one will be anxious to initiate litigation with the idea of having the election declared void because a valid nomination was wrongly rejected. The returning officer acts in a sense judicially: provided that his action is not vitiated by bad faith or partiality (which nobody suggests) he personally is unchallengeable. If it really is his duty to decide whether a candidate is or is not "engaged in the area" in nursing or similar work, and if he decides differently in what appear to be similar cases, there may be no remedy. But it is never a satisfactory situation if the law is made to appear either uncertain or unequal in its application—or both.

In England Now

A Running Commentary by Peripatetic Correspondents

NEVER before this Danish spring have I noticed how pungent yet how pleasant is the scent of the balsam poplar. The two great trees that stand before my window, which for weary weeks were bleak and dead, their roots set in the hard earth with never a blade of grass on it, swiftly clothed themselves in their lovely shimmering leaves, and now bees hum in their topmost branches; in the morning sun the scent is like hot beeswax.

Spring comes to this northern city unbelievably swiftly. Seven or eight weeks behind southern England, then one morning the sun shone and suddenly the woods by the sea were carpeted with anemones, cherries were in dazzling blossom, and men trundled great stone pots filled with tulips and wallflowers and forget-me-nots out into the city squares. Pavements that last week were cold and grey and empty, swept by bitter winds off the Baltic, are now hidden by hundreds of little tables beneath striped awnings; the table-cloths are clipped on and the ends crack merrily in the breeze, for there is always a wind in Copenhagen. The sun shines warmly on the green copper domes and spires, glinting from the golden balls that surmount them; the Townhall carillon plays merrily and ships hoot with joy. People have changed from bundles of woollies and enveloping leather jackets to straw hats and light coloured clothes, and everywhere the flags are flying.

The flag of Denmark is so lovely that the Danes fly it on all occasions—birthdays and weddings, holidays and festivals, or just any day when they feel particularly happy. On Liberation Day, May 4, Copenhagen was hidden by its brave red fluttering flags, and my little English car added to the gaiety of the nations with a Union Jack tied on with string to the wing mirror. Outside the city, too, pennants and full-size flags flew from the tall staff before almost every cottage and farm. Liberation Day was a holiday and the King's Guard marched about the streets all day long in their tall fur hats and their gay blue trousers, the band playing lustily and children running and leaping beside them. In the midst of the rejoicing crowds however one would come quietly on a little clearing on the kerbstone or in one of the great squares, where a wreath and a few bunches of garden flowers lay on the pavement to tell where a Resistance member had died. At night there were torchlight processions and fireworks, and very lovely these looked reflected in the long lakes that were once the city moats. These waters now sport rowing-boats and little anchored rafts where swans are sitting on their high nests. One pair of swans has built an untidy affair of packing straw and cigarette paper right against the water's edge; here no fireworks were lit and by day an awning is put up to shield the pen from the sun; at peak hours a policeman stands guard over her and all Copenhagen awaits the coming of the cygnets.

The storks have arrived and stand proudly on their cartwheel nests on the farm buildings. They seem to be resting after their long flight northwards, standing quietly looking down at the life below, when suddenly without warning the male bird lifts up his long beak and lays it along his back, letting out the startling clapping sound that is his love-song. The owners of a pair of nesting starlings think themselves indeed fortunate; for to the Danes these garrulous birds, so familiar to us, are welcome harbingers of spring. The exiled Englishman looks on them with a certain fondness too, for may they not have wintered in Trafalgar Square?

* * *

We have had almost four years of rhesus-testing, but the ever-possible happened for the first time this week. A woman at the antenatal clinic, pregnant for the second time, presented as part of her previous obstetric history the small white card we give first attenders for them to carry always in their handbags. This bears their name, address, blood-group (ABO and rhesus factor), and, in the case of rhesus-negative women, the rhesus blood-group of the husband if he is rhesus-positive. This woman was of the last category, and our obstetrician raised his eyebrows when he noticed an alteration in our last-line entry: "Husband—Positive." A broad pen-line all but obliterated the last word, and beneath, in determined block capitals, the word "NEGATIVE" defiant. This was no laboratory-correction, obviously, then a new card would have been issued and an panying letter of apology and explanation would have been remembered. Almost before our query, "Who did this?" was out of his mouth explanation followed: "My husband was *simply fur* when he saw *that*! He changed it *there and then. He* in the Navy, and *his* blood-test was *always NEGATIV*

* * *

I hadn't long been in the isolation hospital w a painful complication of mumps before I was introdu to a strange circular relic of the Bronze Age, the bedp If it had been unearthed in the deeper deposits of Chaldean excavations it would doubtless enjoy a tinguished place in the British Museum. I perch myself perilously on this curiously unstable article and very soon realised, with growing dismay, that I was not sitting *on* it but sinking *into* it. Yes, *it had to be accepted*. I was sucked and jammed into this wretched copper coracle. For 20 minutes, with rapidly diminishing strength and dignity, I wrestled to effect a separation. Finally I intimated to a passing orderly that I needed assistance.

In a little while the nurse came. Then the sister came. *And last of all the matron came. They all examined the* situation with a nice mixture of delicacy and practical determination. The student nurse, hot from her physics class, timorously suggested that if only the vacuum could be broken the problem would be solved. She was firmly put in her place. The sister, who had met her Waterloo, looked to the matron. The matron, who had not achieved her exalted position for nothing, said in a commanding voice: "Hold me tight, doctor!" I thereupon threw my arms around her while the sister and nurse worked arduously below. I supported them with many a merry jest and dear encouragement. I felt *I* must put on a courageous front, for much was at stake. In a moment I was free—free as the wren's tongue, and far more lyrical. But the incident has left its mark.

* * *

The *recent animal stories in* the press, particularly that of the bus-driver who found a lion as his only passenger, prompt me to set down a personal anecdote.

It was in the interval between the third and fourth Bechuanaland campaigns, at Impala, the capital of Hotsetotseland. I had been to the *salon of* Dentine ("She was only a settler's daughter but she's lost her Native Reserve") Blatherspoon and was *sleeping off* our conversation in the long grass, which *in those parts* sometimes reaches a height of three inches. All around, herds of voodoo, gnu, urdu, and pushtu were grazing. Suddenly a hippopotamus, playing tig with a Coal Black *Ma'amba, landed with all four feet on* my stomach. Fortunately I had glanced up a moment before and was able to put my abdominal muscles into Defence Position No. 3 in the nick of time, so that he rebounded into the veldt. You would have enjoyed the look of dismay on his face, for, deceived by my grey flannel trousers, he had expected to sink up to the nostrils in the grey, green, greasy Limpopo river.

But the point of the story is this. Some 36 hours later I passed a fine specimen of the emerald-eyed tapeworm (*T. saphira*) and it showed slight but *definite bruising on one side of its head.*

* * *

There's one thing about a Devon man, you can never accuse him of unnecessary hyperbole. This one was huge, with a round red face and blue eyes, and a gentle soothing voice. I was asking him if there had been any history of nervous breakdown in his family. He gave this considerable thought. "Well, no," he said "unless you count my uncle Jarlie . . . he were a bit contrary come the end . . . took seven men to 'old 'im down, I'm told . . . proper contrary 'e were."

* * *

One of the regional hospital boards is, I see, advertising for LOCUM TENENTES. *I hope there will be no* squabbling over games of King of the Castle. Or does the secretary mean LOCA TENENTES or LOCUM SERIATIM TENENTES—or what?

Letters to the Editor

ANOMALIES OF SALARY

IR,—Your leading article of May 20, and the letter n Mr. Stanley Mayne a week later, touch on several omalies of salary within the profession. We would tance still another in which the anomaly is due to the vice of a single Treasury committee—the University ants Committee—but is accentuated by competing partments.

Mr. Mayne points out that Sir Will Spens does not deal h salaried medical officers: this is understandable. ing outside the terms of reference of both Spens mmittees. But in one respect he did go beyond ese bounds. The report on consultant and specialist muneration suggested that whole-time clinical prosors and their staffs should be eligible for the consultant ecialists' merit awards. This was outside his terms reference.

It is implied that no competent clinical scientist would interested in giving his whole time to the study of his bject unless his post were financially competitive with e National Health Service. This may have been ue in 1920–21, when clinical units were initiated, but is not so in 1950. We need scientists trained in ientific method and techniques who have taken not nly the membership or fellowship of the Royal College f Physicians or Surgeons, but also the honours science chools of their university. These honours schools, ith postgraduate research, alone give the basic training eeded by the scientist to apply modern research echnique to problems of clinical medicine.

The suggestion of the second Spens Committee was, urprisingly, accepted by the University Grants Committee, by the Ministry of Health, and by the Treasury. n consequence, whole-time university staffs in the linical years are eligible for two salaries—one from the J.G.C., through the university and school for their eaching, research, and care of patients, and the other, lso for care of patients, payable for special merit, from he National Health Service through the university and school. This principle of dual remuneration is entirely new in British finance.

The reason given for the principle of dual remuneration is not valid. In any case it is foreign to the true spirit of university life. But since it has been accepted by the Treasury it needs re-examination in the light of present-day social problems, and of its repercussions upon other university faculties and other branches of the profession in this country and the Dominions and Colonies. We are well aware that, despite the increase in salary in other university faculties, there are some serious anomalies, among both the distinguished and the undistinguished, in favour of medically qualified scientists.

The real *gravamen* of our letter is, however, that within the faculties of medicine of the universities of this country the U.G.C. has set up different salary-scales for preclinical and clinical workers of the same grade. It would be generally agreed that the clinician whose name is on the bed-ticket, who takes the final decision on treatment following advice given by his paraclinical and preclinical colleagues, and who is responsible for his case day and night, is entitled to more remuneration than his paraclinical and preclinical colleagues. This is properly represented by the 10–12·5% difference in scales in the professorial grades. But in the lowest grade a medically qualified scientist begins as assistant lecturer at £600 per annum in the preclinical grade or at £900 per annum in the clinical grade—a difference of 50%. This is a matter of moment to the young man who, at the beginning of his career, is likely soon to face problems of family or housing.

In 1947–48 the Conference of Non-Clinical Medically Qualified Professors presented evidence that of the total vacant non-clinical posts (including at that time pathology and bacteriology), 40% remained vacant, and for 30% there was only one applicant. There is evidence that in 1950 the position is not much different: the good work of the Goodenough report has been undone by the U.G.C. and the National Health Service conditions—that is, by the Treasury. Not only is there financial encouragement to the young medical scientist to enter a clinical department rather than a non-clinical, but there is also Government-supported demand from the Medical Research Council, the Ministry of Supply, and in many cases the Services, all of which bodies are outbidding the preclinical departments of the universities for the new recruits among the honours graduates in science with medical qualifications. Moreover, the requirements of Government departments appear to be growing.

If the intention of the Government and the University Grants Committee is to staff the preclinical departments with personnel lacking medical training and qualifications, then the policy is understandable. It may be that they wish the training of the doctor and medical scientist to be effected in these years by only the second best; this again will happen on this policy.

It is not really in the best interests of the profession, the universities, or the National Health Service that an anomaly of salary should exist which tends to attract the young man on the threshold of his career away from the preclinical university departments.

TOWARDS SAFETY IN BOXING

SIR,—Your annotation of May 27 on cerebral injuries during boxing is appropriate for a medical journal, especially as a good proportion of doctors have at one time or another represented their university and hospital in boxing competitions. The thirty-six cases of intracranial hæmorrhage reported by Jokl immediately bring home the danger beyond dispute. The practical considerations advanced in your article equally clearly show the difficulty, or impossibility, of avoiding this danger by medical anticipation.

Nevertheless, an " attitude of mind " on the part of referees and spectators, as well as contestants and their team-mates or their professional equivalents, will do much. Thus recently when a team of men belonging to the Amateur Boxing Association met Services' representatives, the referee stopped several contests at a stage when such intervention would formerly have been regarded as premature, badly judged, and " soft." I remember a contest in which a patient was " out on his feet " after rising from a count of 8 seconds, and his experienced and anxious second jumped into the ring to stop the fight. The referee ordered him out (it was an O.T.C. event) and the time bell just saved the situation. Even so this lad had *retrograde amnesia* for the whole contest of three rounds and for some minutes before it began.

Serious injury may occur like a bolt from the blue where the recipient is perfectly fit and strong and fresh; but this is very rare. In most cases such injury is inflicted on a man who is already severely affected physiologically, if not pathologically, and who is at that time unable to offer any real defence. I would strongly support any measures or interpretation of rules that would minimise the incidence of serious damage during boxing, and in addition the encouragement of an " attitude of mind " that will permit the referee to stop a contest before a man is dangerously incapacitated, without there being any sense of loss of honour or absence of " guts." This should be true for all contests, but is particularly important where circumstances have permitted opponents of unequal skill and strength to face one another in a contest which is almost inevitably lost before it begins.

London, W.1. S. L. SIMPSON.

THE FLOW OF LYMPH

SIR,—This subject, which was discussed in your leading article of March 11, seems to have been somewhat neglected; and I should like to add some observations of mine.

The blood is—except in the region of the digestive tract—the only source of lymph, and it is without exception the only outlet for lymph. Thus the velocity of the lymph-stream must be adapted to the local and general rate of lymph production. Since the production of lymph depends greatly on the local state of blood capillaries, local is more important than general adaptation. Where the permeability of blood capillaries is greatly increased, the inflow of fluid to the tissues increases correspondingly. When simultaneously the outflow of lymph is checked—as by inactivity of a broken limb—œdema results. In itself this œdema is not dangerous, except when it involves the lungs. Pulmonary œdema may be fatal; but the body has a means of protection against this danger.

Pulmonary œdema develops rapidly, because lymph flows through the lungs very rapidly.

I have seen a dog, on the third day after phosgene poisoning, which was definitely recovering and in good condition. This animal was killed instantly by the intravenous injection of a 25% solution of magnesium sulphate. The animal fell immediately after the injection, and from its nose started to run a stream of clear plasma. In the few seconds between the arrest of respiration and of the heart action more than 100 ml. of plasma was shed from the nostrils; and much remained in the lungs, forming profound œdema. Before the injection this animal clearly had no pulmonary œdema, but its lungs had not recovered completely from the phosgene poisoning and were still predisposed to œdema; and this was precipitated by the arrest of respiration, which stopped the normal lymph outflow from the lungs.

I have also observed the velocity of lymph-flow in the lungs of rabbits.[1]

In these experiments an indian-ink suspension was injected through the chest wall directly into the lungs and the animal killed immediately by bleeding; death occurred a few minutes after the injection of indian ink. Post-mortem examination showed no trace of indian ink in the lungs; *it had been washed out within a few minutes by the lymph-stream* (which was accelerated by the laboured respiratory movements preceding death). But when, immediately after injection of indian ink, an artificial pneumothorax was established, the indian ink remained in the lungs as long as the pneumothorax was sustained—in my experiments for three days. The ink was found post mortem as a blotch over the whole cross-section of the lobe except in the hilar region, where the lymph-vessels were compressed by the retracted lung. Arrest or checking of outflow of lymph-containing toxic products from the lung seems to be an explanation of the detoxicating action of pneumothorax in pulmonary tuberculosis.

It seems therefore justifiable to assume that the flow of lymph through the lungs is very rapid and is mainly sustained and regulated by the respiratory movements. Whenever fluid begins to accumulate in the lungs, and thus the danger of pulmonary œdema develops, changes in expiration can be observed.

In dogs poisoned with phosgene these changes were in three phases: at first expiration became prolonged; then laboured; and finally "groaning." In this last phase expiration begins with a closed glottis, which opens suddenly giving rise to a groaning sound. In each of these phases expiration is prolonged and the air-pressure in the lungs increased. This increase is especially great in the third phase, and thus the outflow of fluid from the lungs must then be consi increased.

I later observed "groaning" expiration c in cases where the *permeability* of lung cap and consequently the flow of fluid from the blood the lungs, was increased—e.g., in a case of int with petrol vapour, in extensive pneumonias, and pulmonary congestion due to heart-failure.

The dilution of blood which takes place during period of remission after the phosgene poisoning indirect proof of the escape of fluid from the blood the lungs.

The escaping fluid is plasma; this coagulates on damaged lung, covering it with a layer of fibrin[2] changed to serum, which is forced out through the l vessels back into the blood-stream. Consequently occurs after phosgene poisoning an intravenous auto-in of serum.

In experiments on dogs I have shown[3] that intraven injection of the animal's own serum causes dilution of bl just like that during the period of remission after t phosgene poisoning. After a single injection of serum, have noticed a decrease in the red blood-cell count to 8 of the original value 7 hours after the injection. When t injection was twice repeated, the dilution of blood took pl more rapidly, reaching the same level $4^1/_2$ hours after the fi and 2 hours after the second injection.

It seems that the changes in expiration described abov which counteract accumulation of fluid in the lun may be an important clinical sign in cases where the is danger of pulmonary œdema. This danger mig thus be recognised earlier and averted more promptly.

Ely, Cambridgeshire. H. Z. E. SCHEURING.

DEATH OF A MIND

SIR,—As a labouring man I am not-expected to r the professional periodicals, but circumstances compel me long ago to follow your pages. I read with more tha ordinary interest the article of May 27 on the Deat of a Mind. I disagreed with this title. There is n death to the mind—to the brain, yes. The writer show wonderful insight into mental phenomena. The stor had a gripping interest for me.

Caversham, Reading. MCKINLAY HARGREAVES.

A URETHRAL SYRINGE

SIR,—In your issue of April 8, Mr. Riches describes a urethral syringe consisting of a glass nozzle and a rubbe bulb. He states this is suitable "for aspiration o irrigation of an indwelling catheter," and "after an form of closed prostatectomy this syringe can be use for aspiration of the catheter in case of blockage." Th Canny Ryall syringe is condemned as "unsuitable fo irrigation of a catheter because the nozzle does not giv an airtight fit." Exactly the same objection would seen to apply to the Riches syringe; only the danger-poin *here does not lie between the nozzle and* the cathete but between the rubber bulb and the nozzle. Who is t say that after a few boilings an air leak will not develo at this point and may not be detected until too late It is not the leak that matters but the fact that th air may be reinjected into the bladder. Aspiration o air into the bulb is, of course, more likely to occur shoul there be a temporary blockage of the catheter.

My experience of opaque syringes and other opaqu instruments for aspirating the bladder is particularl painful. Many years ago I was using a Bigelow evacuator to clear away clot. There was a leak betwee the catheter and the rubber bulb sufficient to allow large quantities of air to enter the apparatus, the result of which was amply demonstrated at the early autopsy

At the Newcastle General Hospital it was our custon to use all-glass syringes of about 2 oz. capacity (of the o Clinic type) for all bladder irrigations and aspira- after punch prostatectomy. Any air leak was ced at once. There was a period during the late war n these syringes were unobtainable and we had to on all-metal syringes for the purpose. Four patients one after the other from reinjection of air before real fault was discovered. Thereafter opaque nges of any type were *forbidden*, and such stocks re possessed were destroyed. That was the end of employment of the urological equivalent of the cle pump.

PERFORATION AND HÆMATEMESIS

IR,—In his article of Feb. 11, Mr. Ives emphasised rarity of hæmatemesis and perforation occurring ether. In the cases cited by him there is a certain se of time between those two incidents. In the owing case perforation and hæmatemesis occurred ultaneously.

stonemason, aged 44, was admitted to hospital one after- n with a two-year history of pain in the epigastrium made se by food, which caused vomiting. The history was ical of gastric ulcer.

he next morning, at 7 A.M., he started vomiting blood, l immediately afterwards began to have intense abdominal n. His pulse was very rapid and of small volume; his domen was very rigid, and he had all the signs of peritonitis. His condition being too poor for surgical intervention and a table blood-donor being unobtainable, conservative treat- nt was started. He was given morphine and atropine d an intravenous glucose-saline drip. Continuous suction s applied to his stomach.

The hæmatemesis did not recur. His general condition proved a little, but never sufficiently to allow a laparotomy. e next day he began to hiccup, and he died 36 hours after perforation and hæmorrhage.

Moka Hospital, Mauritius M. Shun Shin.

N.O.T.B. ASSOCIATION

Sir,—Medical practitioners who are taking part in the pplementary ophthalmic service or are interested in hthalmic practice may like to know something about e N.O.T.B. Association, which was formed in January, 49, to carry on the work of the old National Ophthalmic reatment Board.

All ophthalmic medical practitioners whose names are on e central professional list, and all dispensing opticians ho are members of the Guild of British Dispensing pticians, are eligible for membership; the present medical embership is 662. The association is administered by a mmittee composed of 4 ophthalmic medical practitioners ppointed by the Ophthalmic Group Committee of the British edical Association, 4 ophthalmic medical-practitioner mem- ers of the N.O.T.B. Association elected by the medical embership, and 7 dispensing members appointed by the uild of British Dispensing Opticians. It has a medical ecretary and secretary, the day-to-day work being carried out y four subcommittees. Three medical members appointed y the committee represent the association officially on the phthalmic Group Committee.

The objects of the association are: (1) to facilitate a edical eye examination for the general public; (2) to reserve the liaison between ophthalmic medical practi- ioners and dispensing opticians; (3) to encourage the evelopment of adequately equipped and staffed eye entres throughout the country for the convenience of he general public in areas where the permanent eye ervice is not in operation; (4) to act, if called on, in an dvisory capacity in any difficulty which may arise etween members of the association; and (5) to deal ith any queries which may be raised, and to provide eneral information.

The committee invites all those who are eligible, to support these objects by joining the association. The annual subscription is £1 1s.

M. H. Atkins
Secretary.

SULPHONES IN LEPROSY

Sir,—In connection with your leading article of Jan. 28, I should like to mention briefly my experience at this hospital.

Four cases of lepromatous type have been on sulphone treatment for the last two years; they have had a 25% solution in arachis oil 3–5 ml. subcutaneously twice a week.

Another four cases of similar type have had 'Sulphetrone' as a 50% aqueous solution in normal saline 3–7 ml. subcutaneously biweekly.

A further three cases of similar type have had 'Promocitin,' six tablets per day for eight months.

In each of these three groups the clinical response has been good, but the bacteriological response poor.

Government Pentland Hospital,
Vellore, South India.

P. V. Karamchandani.

TRAINING FOR GENERAL PRACTICE

Sir,—The B.M.A. report on the *Training of the General Practitioner*[1] includes among the family doctor's duties "health education and preventive medicine." This led me to hope for proposals for incorporating a modicum of instruction on these subjects in the three-year training to be undertaken between qualification and entry into practice. I was not really surprised to find no further reference; the customary lip-service had been paid.

Professor Neale, in his letter of May 27, suggests that, for an all-round postgraduate course for general practitioners, the D.P.H. course—containing instruction in the epidemiologies of the home, the factory, the school, and even the hospital—cannot be bettered. In principle this is true; but the D.P.H. is a statutory requirement for those specialising in public health, and it should be recognised as a specialist qualification. However, it is most important that general practitioners should have a course of study in the principles and practice of preventive medicine and health education; this should certainly be provided in the three-year preparatory training after qualification.

London, N.W.8. P. A. Tyser.

SUBSTITUTES FOR CURARE

Sir,—In your leading article last week the statement was made that "it is not yet clear that C10 possesses any advantages over the natural drug."

It has been shown[2] that C10 is in fact superior to *d*-tubocurarine hydrochloride, since in equipotent doses (as judged by degree of muscular relaxation) the former drug leaves the patient with a significantly greater vital capacity than does the latter. Moreover, C10 appears to be free from side-reactions, whereas most workers have had the common experience of bronchospasm and histamine release as concomitant effects of the action of *d*-tubocurarine hydrochloride. To my knowledge the evidence produced in support of these conclusions has not been challenged.

Since that report appeared C10, in association with thiopentone, has been used routinely at the Maudsley Hospital for modifying electrically induced convulsions. Between February, 1949, and February, 1950, 973 treatments were given to a total of 125 patients. The only untoward effect was undue cyanosis in 2 cases, due to faulty technique in the management of the patient while natural breathing was being re-established after the fit. Both patients made uneventful recoveries. One of these was given 20 mg. of C5—the only occasion in the series when an antidote was thought necessary. The absence of side-effects, and of any evidence pointing to idiosyncrasy, in such a large series, clearly establishes C10 as the drug of choice for this work.

---

[1] See *Lancet*, May 27, pp. 1001, 1008.
[2] Davies, D. L., Lewis, A. *Ibid*, 1949, i, 775.

That C10 should act for a shorter time than *d*-tubocurarine hydrochloride is an advantage to the psychiatrist, since the maximum paresis is obtained in the fourth minute, when the fit is induced. No single instance of delayed recovery was noted in the series here described.

Altogether it seems that for the psychiatrist C10 has a proved superiority over *d*-tubocurarine hydrochloride.

Institute of Psychiatry,
University of London.

D. L. DAVIES.

EPIDEMIOLOGY OF POLIOMYELITIS

SIR,—Dr. Cavendish Fuller's comments (May 13) on my letter of March 25, are rather sweeping. He asserts, without giving any references, that epidemic disease cannot be spread by fæcal pollution of the permanent way. A moment's reflection on the countless thousands of miles of railroad in constant daily use on this tightly packed island, carrying passengers a small proportion of whom are bound to be excreting typhoid bacilli, dysenteric organisms, or the virus of poliomyelitis, is sufficient to cause the epidemiologist to consider this mode of spread.

The Railway Executive, in a recent statement, makes these observations:

> "Although many investigations have been made, no country in the world has so far found any better solution for its railway coaches. The chemical closet and similar devices used in aircraft, etc., are not suitable as they stand because (*a*) there is not sufficient capacity, (*b*) they bring inside the vehicle problems of æsthetics, smell, contamination, and possible misuse which are at present entirely absent. Any system inside the coach involves special means of disposal and this is distasteful work for which it is likely to be difficult to obtain staff. As intimated above, the problem will continue to be examined with a view to seeking a solution and the research department will take a leading part in these investigations, but there is no alternative for the time being to the continuance of the previous practice so far as the new coaching stock is concerned."

M. B. MCCANN
Worksop. Medical Officer of Health.

ALBUMIN-ACTIVE ANTISERA IN RHESUS TYPING

SIR,—Dr. E. M. Stirk's paper (May 13) on the use of albumin-agglutinating antisera calls for criticism on a number of points, some of which have already been dealt with by Dr. Richardson-Jones (May 20) and Dr. Malone (June 3). Everyone will agree that all patients who are to receive transfusions should be Rh typed, but the general policy and detailed proposals of Dr. Stirk are probably not the best way of achieving this end. The main problem appears to be that of supplying sufficient reliable testing serum to the smaller hospitals where only relatively few transfusions are carried out. Larger hospitals and those laboratories which serve several hospitals will perform enough Rh tests for their pathologists and technicians to be able to obtain experience and to produce reliable results with almost any of the proved methods of Rh testing, including the use of albumin-agglutinating antisera in precipitin tubes, and perhaps even by the capillary-tube technique. There is little doubt that the most reliable method of all is the use of a saline agglutinating antiserum in precipitin tubes; and every effort should therefore be made—and in most regions it is being made—to supply small and occasional users with such antisera. But on the whole when a transfusion can be planned some days in advance, it is always best for both the testing of the patient's blood and the matching of the blood for transfusion to be done at the regional transfusion centre.

Certainly it is important that all possible use be made of albumin-agglutinating antisera—i when any patient is found to have a usable serum sort, the quantity of blood drawn should depend on condition and not solely on the day-to-day needs of laboratory. All serum which is to be used for Rh t should have its antibody contents determined by specialist laboratory. While it may be true that an and anti-E are somewhat less common in those which do not agglutinate any cells suspended in al than in those which do give such agglutination, attempt to base the supposed antibody content of a se on this criterion is a retrograde step. Up to 1944 it perhaps necessary to guess the antibody content serum and to use several antisera for each test in one of the sera was wrongly classified. Such a meth is at the present time unjustifiable. It is indeed surpris that Dr. Stirk always obtained agreement between different sera. They must by chance all have been p anti-D or all anti-C + anti-D. The latter supposit seems more probable, since according to Mollis Mourant, and Race[1] the total frequency of D-negat persons in England is 16·8%, of whom 16·0% are negat both with anti-D and anti-C, agreeing somewhat m closely with Dr. Stirk's figure of 14%. It is most import that transfusion recipients who are negative to anti but positive to anti-C should be classed as Rh-negati It is also a possible source of error to use anti-Rh testi sera containing anti-A or anti-B agglutinin. This another reason why all Rh testing sera should be iss from specialist laboratories since only such a laborat is likely to have facilities for carrying out and check the necessary absorptions.

PERFORATED PEPTIC ULCER

SIR,—In their article of May 13 Mr. Truscott a Mr. Withycombe give their reasons for rejecting co servative treatment for perforated peptic ulcer exce in special circumstances. On comparing the five fa cases in their series with the series described by M Hermon Taylor,[2] I am struck by the relatively lon period between the time of perforation and the time admission to hospital in their series. Mr. Hermo Taylor describes twenty-eight cases in which (with th exception of one patient whose ulcer had been perforate for 24 hours, and who was unfit for any type of trea ment) the average time between perforation and admissio to hospital was 3 05 hours, and the longest time 8 hour By contrast with this, in the five cases described Mr. Truscott and Mr. Withycombe the average time perforation was 11·2 hours, the shortest being 7 hou and the others ranging from 10 to 15 hours.

It would seem, therefore, that operation is advisab in cases where perforation has been present for 9–10 hou or more; and it is probable that if this rule had b followed in the series reported by Truscott and With combe the fatalities in cases treated conservatively wou have numbered one (instead of three) out of twenty, a their conclusions might have been quite differe Mr. Hermon Taylor stated in his article that "ca perforations will seal themselves if the stomach is k empty by *aspiration*." *This suggests* the value immediate aspiration carried out by the general prac tioner if the patient cannot be got to a hospital with a few hours of the onset of symptoms.

It appears that both methods have their danger conservative treatment is dangerous when more dra treatment is required, and operative treatment dangerous when the patient is unfit (usually because some other disease) to stand it. Therefore whicher

WATER AS A NUTRIENT

IR,—Wholesome water, with or without its traces of eral ingredients in solution, is the protective food excellence. But any attempt to make it the vehicle other substances which current knowledge regards necessary in our diet, such as calcium, fluorine, and ine, should be considered very critically. If the nan requirements of these trace ingredients are ictly known, and if it can be said with certainty it the average mixed diet is deficient in one or more these elements, and if the only, or even the best, way making good these deficiencies is by introducing them ı the public water-supplies, then it would be "cutting one's nose to spite one's face" to refrain from doing ; but these are very big ifs. Is the suggestion to nvert water into what would amount to a diluted edicine simply another phase of the modern complex r faking, in some way or other, nearly every article food we consume? One does not need to be specially nical to detect the ulterior motive behind most of the louring, bleaching, pasteurising, sterilising, polishing, id fortifying that is applied to much of the food we onsume today. So every proposal to fortify food or ater with minerals, vitamins, &c., should be judged rictly on its merits after due study and research.

The elements whose presence in water constitute it nutrient [1] are fluorine, iodine, and calcium.

Present knowledge suggests that water containing more than one part per million of fluorine is liable to cause luorosis or mottled teeth in children, while dental caries follows the consumption of water containing appreciably less than this amount. If water were the only source of fluorine, it would seem that here, at any rate, we have the very knowledge we want of the knife-edge *optimum* amount of fluorine to add to or remove from various supplies, and the action that Murray and Wilson [2] recommend in adjusting supplies to contain 0·5 p.p.m. fluorine would be justified. But does this take account of the very unequal amounts of water consumed by different people; of the fact that fluorine might be concentrated in some cooking processes and entirely removed in others; and of the fact that water is not the sole source of fluorine (fluorine has been recorded in baking-powders, butter, and other foods, and probably occurs in many fruits and vegetables, as eaten, from the use of insecticides containing the element)?

Is fluorine deficiency the only or even the main cause of dental caries? They may be associated but yet not necessarily be cause and effect. It would be interesting to know what percentage of the population does not suffer from fluorine deficiency. After all, we have evolved in our environment as it is; *and would it* be any less reasonable to try to establish, say, a deficiency of argon in the atmosphere we breathe than a deficiency of fluorine or anything else in the very mixed diet that we can eat if we choose wisely?

If our present dietary deficiencies are due to an obsession for consuming manufactured, pre-packed articles whenever possible, is it the proper corrective to superimpose yet another artificial process—viz., fluorising—on our water-supply, which we already sometimes aluminate and almost *universally* chloraminate, or has the time come to call a halt to these artificial means and to start the reverse process of getting back a little nearer to nature?

Iodine is another element only required in trace amounts by the human body, the average daily requirement for adults being estimated at 0 05 mg. Most people obtain all they require from water, sea fish, and vegetables, but the use of iodised table salt and the inoculation of water-supplies with small amounts of iodides are already fairly widely practised. Only if the success of these measures can be proved is their further adoption justified.

The deficiency of calcium in many diets, of which there seems to be no doubt, is surprising in view of the prevalence and cheapness of the element. In considering public water-supplies as the channel for introducing extra calcium into the diet, a number of considerations must be borne in mind. In the first place, natural water-supplies vary enormously in their calcium content, soft supplies from the Welsh hills containing no more than 20 p.p.m., whereas supplies derived from lowland rivers may contain up to 160 p.p.m. and supplies from miscellaneous wells up to 350 p.p.m. Taking the daily requirement of calcium as 1000 mg. (a low estimate probably) this would be supplied by 1½ pints of milk, or 5 oz. of cheese, or 6 oz. of vegetables. To replace 1½ pints of milk one would require, of soft water, of hardness 5, as much as 88 pints, assuming the hardness was due to calcium salts and not to magnesium. Of hard water, say, hardness 20, one would require 22 pints. If some of the hardness were due to magnesium salts, a bigger volume still would be required to supply the needed amount of calcium.

It is not to be supposed, of course, that there is any intention of taking the whole of one's calcium requirement in one's water-supply. Nevertheless, it is obvious that, by comparison with other substances, particularly dairy products and vegetables, the calcium one derives from average water is negligible, and even from very hard water almost negligible unless one consumes relatively enormous amounts. Moreover, in cooking, much of this calcium might go out of solution, forming a deposit on cooking utensils and becoming unavailable.

USE OF POLYESTER RESINS IN MEDICINE

SIR,—Some omissions from the article by Dr. Scales (April 29) may give your readers an erroneous impression—especially as his use of references in some parts of his paper shows that he is well aware of the custom of referring to earlier work in relevant fields. Writing on Reproduction of Bones he does not mention the articles on Plastic Bone Models in the *British Medical Journal* (Feb. 25, 1950, p. 482), and on Plastics Aid in Medicine in *British Plastics* (November, 1949), in which attention was drawn to the pioneer work done in this field by my company's laboratories, based on Blaine's original work which goes back quite a few years.

Whilst one could perhaps make no claim to originality in reproducing bones in plastic material (except perhaps that to my knowledge no-one produced a complete, articulated, all-plastic skeleton before Blaine's development work in this connection) it would appear a matter of scientific accuracy (which, after all, is what your readers are looking for, both at present and in future) and courtesy to make some relevant references.

Educational & Scientific Plastics Ltd.,

Croydon, Surrey.
T. W. FAZAKERLEY
Managing Director.

*** We have shown this letter to Dr. Scales, who writes: "The article to which your correspondent refers makes no claim to originality in bone-casting. It simply states a method that was developed at Stanmore, and which, as far as I know, has not been previously described. Considerable doubt seems to exist as to who carried out the 'pioneer' work in this field. Following the article in the *British Medical Journal* of Feb. 25, there appeared in that journal (March 25, p. 731) a letter by Dr. R. A. Broderick, which should be read by

1. Leading article, *Lancet*, 1945, ii. 17.
2. Murray, M. M., Wilson, D. C. *Ibid.* p. 23.

those interested. There is no reference in *British Plastics* of November, 1949, to any work by Dr. Blaine. No doubt the reference is to an article which appeared in *British Plastics* in December, 1949, in which the writer states (p. 638): 'These models have always been produced in some artificial material such as plaster-of-paris and gelatin.' If Dr. Blaine is concerned with scientific advancement, surely his methods of bone-casting, which may be of interest and use to many people, should be published. Mr. Fazakerley should not complain if no reference is made to methods which have not been published."—ED. L.

ULCERATIVE COLITIS

SIR,—In his letter last week, Dr. L. Rau quotes me as holding the opinion that for all practical purposes the psychological aspects of ulcerative colitis can be ignored. I must disclaim any such opinion. On the contrary, I have for many years believed and taught that psychological factors play an important, if not the most important, part in ætiology, and that psychotherapy, in selected cases, is a valuable adjunct to treatment.

Birmingham. T. L. HARDY.

A.C.T.H. AND LYMPHOSARCOMA-CELL LEUKÆMIA

SIR,—Your leading article of Jan. 28 mentions that Pearson, Eliel, and Talbot, in a symposium held at the New York Academy of Medicine on Jan. 13, describe "diminution in the size of the spleen and lymph-glands in chronic lymphatic leukæmia, lymphosarcoma, and Hodgkin's disease, and a remission in five cases of acute leukæmia" after application of adrenocorticotropic hormone (A.C.T.H.).

Unaware of the findings of these workers, my colleague, Dr. Hassan Darman, reported to the Turkish Medical Association of Istanbul, on Feb. 21, the following observation:

A young man, aged 26, had suffered for 11 months from increasing weakness and debility, coupled with violent pains in the region of wrists and ankles, with concurrent swelling of the lymph-nodes of the neck, axilla, and groin. For 2 months the patient had shown manifestations of diabetes insipidus—excessive thirst and excretion of 4–5 litres of urine per diem.

The affected glands were swollen to the size of walnuts or hazelnuts. Near the junction of the 5th rib and the sternum was found a walnut-sized tumour, obviously separate from the bone. Insteps and ankles were extraordinarily painful, and both legs were almost completely paralysed—apparently through pressure of enlarged lymph-nodes upon the main nerve-trunks in the pelvis.

Blood examination: red cells 1,700,000 per c.mm.; Hb 40%; white cells 3600 per c.mm., of which 93% were atypical lymphocytes (lymphosarcoma cells). The sternal-puncture smear consisted almost entirely of the same cells; normoblasts 17%. Examination of an inguinal lymph-gland, which showed many mitotic cells, led to the pathological diagnosis of lymphosarcoma. X-ray examination revealed decalcification and osteolytic foci in several bones of the foot. The sella turcica was about normal size; but it seemed that the diabetes insipidus was most probably caused by a proliferation of osseous tumour tissue, encroaching upon the hypophysis.

Clinical diagnosis: universal lymphosarcomatosis with leukæmic blood picture.

In order to combat the diabetes insipidus, this extremely ill man was treated with 'Postuitrin,' a locally produced extract of the posterior lobe—at first 80–110 international units (8–11 ml.) per diem, later 3 ml. per diem. On the 5th day of treatment the patient felt better; the pains in joints and bones had decreased. Blood examination now showed 34% polymorphonuclears and 66% lymphocytes. On the 14th day the glands had become much smaller and the pains had ceased completely.

Thereupon Dr. Darman used another posterior-lobe extract —'Infundin' (Wellcome)—and within a few days the state of the patient had again greatly deteriorated. Blood examination: 86% lymphocytes with only a few polymorphonuclears. Consequently we returned to treatment with the produced extract, and once again the state of the improved.

He has taken this preparation continuously since 1949. His state is very satisfactory; he has develope enormous appetite and is clearly acquiring layers of the abdomen. He has the air, no longer of a suffering but of one who is convalescent. His lymph-glands disappeared almost completely. Although formerly nearly completely in both legs, he is regaining control muscles, notably the iliopsoas and the quadriceps. picture: red cells 2,500,000 per c.mm, reticulocytes Hb 59%, white cells 7200 per c.mm. (polymorphon 37%; lymphocytes, which resemble normal, 63%). bone-marrow contains numerous normoblasts, myel and metamyelocytes and gives the impression of very regeneration.

A further biopsy, carried out when the size of the l glands had much decreased, showed only few mitotic there were strands of connective-tissue with few cells, also still agglomerations of pathological cells.

We were especially impressed by the fact that locally produced extract—but not infundin—sho itself beneficial; and bearing in mind the fact[1] A.C.T.H. applied to rabbits and mice greatly red the thymus and lymph-glands, we concluded that local extract must contain A.C.T.H. Nothing is kn about any beneficial influence of posterior-lobe horm on lymphatic tissues, whereas it has been repeat observed that basophil anterior-lobe cells, in nests strands, can intrude deeply into the posterior l Thus we are convinced that A.C.T.H. has a dama influence not only on normal lymphocytes but als lymphosarcoma cells.

The cortical steroid hormone which under the influ of A.C.T.H. acts upon the lymphocytic apparatus w not seem to be identical with deoxycortone either or combined with vitamin C. For, according to Profe Frada (Feb. 18, p. 329), even large doses had onl "moderate, transient, and inconstant effect u leukæmia." On the other hand Law and Spe found in mice with spontaneous lymphoid leukæ a decrease of the immature lymphocytes after inject adrenal cortical extract, and a regression of infiltrated thymus and lymph-nodes and to a les extent of the spleen.

The preparation employed by Dr. Darman, *appli to two healthy people, led to lymphopenia* after 3 hour this resembles the effect of highly purified A.C.T.H.[3]

The Glasgow Smallpox Outbreak

BETWEEN March 26 and April 1, there were 21 ca of smallpox in the Glasgow area,[4] the original case be in an Asiatic seaman who landed at Tilbury on March

The outbreak has been discussed by Dr. Stuart Laidl the medical officer of health, and Dr. W. A. Horne, senior deputy.[5] They refer to the difficulty of differ tiating clinically between varicella in an adult and var modified by previous vaccination, especially in Asiat "it is imperative to regard an eruption in an Asi showing any varioloid feature whatever as 'adminis tive smallpox' and to carry out timely vaccinatio all contacts." The outbreak provided a sad remin of the vital necessity to protect hospital nursing st by adequate vaccination before recruitment and at reg intervals thereafter. Furthermore: "The value infant vaccination has been established, and the 30- increase in the number of infants vaccinated during outbreak indicates both the serious position result

the repeal of compulsory vaccination and the ıgness of parents to have their children vaccinated ıe presence of danger." All the fatal cases were in ıccinated or unsuccessfully vaccinated people; and, ersely, those patients survived who had been essfully vaccinated, even though only in infancy. lly: "It is of fundamental importance to sustain fficient public-health service of knowledgeable and rienced medical officers, a service still available threatened with extinction due to failure to recognise entive medicine as an indispensable element in an grated National Health Service. Nothing that has ırred in this outbreak has lessened our conviction ; the control of infection in an area is best served the co-ordination of fever and tuberculosis hospitals one group under the direct control of the medical er of health."

Births, Marriages, and Fertility in 1948

n 1948, the birth-rate in England and Wales fell from high figure reached in 1947, but it was higher than the immediate pre-war years; and the stillbirth-rate s again the lowest recorded up to that time. The rriage-rate was maintained at a comparatively high el, but the number of divorces was 27% lower than in previous year. These facts emerge from a report by Registrar-General[1] which includes the following ures.

Population.—The national population (inclusive of Armed rces and merchant seamen at home and abroad) was ,502,000, compared with 43,050,000 in 1947—an increase 452,000.

Births.—There were 775,306 live births in 1948, which presented a birth-rate of 17·8 per 1000 total population. his was a decrease of 2·7 per 1000 from the previous year's ıte. The 1947 rate of 20·5 per 1000 was the highest since 21; and despite the fall, the 1948 rate was still much igher than that of the immediate pre-war years, the average ıte for the years 1936–40 being 14·7 per 1000.

There were 41,574 illegitimate live births, compared with 6,603, 53,919, and 63,420 in the years 1947, 1946, and 1945. hown as proportions of the total numbers of live births, hese figures represent 5·4, 5·3, 6·6, and 9·3%.

Stillbirths numbered 18,399, representing a rate of 23·2 per 000 live and still births, compared with 21,795 and a rate of 4·1 per 1000 in 1947. The rate in 1948 was the best ever recorded in this country up to that time; the provisional rate for 1949 was 22·6.

Fertility.—Of the legitimate maternities during the year, 44·1% were to mothers with no surviving previous children, 30·7% to mothers with one surviving previous child, and 13·3% to mothers with two. There were 9687 maternities resulting in multiple births, of which 2 were quadruplets and 88 triplets. All the quadruplets were born alive. Of about 112,000 confinements which took place within 11½ months of marriage, some 62,000 occurred within 8½ months; and of these, about 42,000 occurred within 6½ months.

Obituary

MORRIS BENJAMIN BRODY

M.D. SHEFF., D.P.M.

Dr. M. B. Brody, who recently died in Sheffield, was one of the most capable and promising among the younger generation of British psychiatrists.

Born in Sheffield in 1912, he graduated M.B. with honours at Sheffield University in 1934, and after holding house-appointments at the Sheffield Royal Infirmary and the Miller Hospital, Greenwich, he decided to specialise in psychiatry. He held appointments at St. Lawrence Hospital, Caterham, and at the West Riding Mental Hospital before he moved to Runwell Hospital, where during the next nine years he established his reputation as an excellent all-round clinician and a successful research-worker. He took the D.P.M. in 1937 and his M.D. degree in 1941. For several years he was honorary secretary of the clinical psychiatry subcommittee of the Royal Medico-Psychological Association and a member of the council of the psychiatric section of the Royal Society of Medicine. From 1946 to 1949 he was deputy medical superintendent at Graylingwell Hospital, Chichester, and last year he was appointed director of research at the same hospital.

Dr. Brody founded the East Ham child-guidance clinic and started the social psychotherapy centre at Graylingwell Hospital. Of his contributions to psychiatric research, his studies on the measurement of dementia and on intelligence tests in the psychoses have gained him a well-deserved reputation far beyond this country; but his lively and original mind did not permit of narrow specialisation. In 1946 he published, in this journal, together with T. C. Hall, his invention of an automatic pneumo-encephalographic apparatus. In psychotherapy he experimented with a short-term method of his own. In his approach to psychiatric problems he was nonconformist and he never tired of questioning and challenging accepted authority. As a teacher he was stimulating and provocative; as a colleague he was loyal and generous. One of the few friends who knew of the shadow of ill health which threatened Dr. Brody writes: "in his professional and private life he radiated vitality and cheerfulness, and even when he was aware that he was doomed he continued with his work undeterred and completed an exhaustive review on mental testing in psychiatry which bears witness to his profound knowledge."

Dr. Brody leaves a widow and two children.

EDMUND CECIL SALT

B.A., M.B. CAMB.

Dr. E. C. Salt, who died at Burton-on-Trent on May 17, at the age of 78, was the son of the Rev. T. S. Salt, vicar of Curbar, Derbyshire. From Repton School he went to Cambridge, where he graduated B.A. in 1893 and M.B. four years later. As a student at the London Hospital one of his contemporaries was McAdam Eccles, who became his intimate friend.

After qualification Salt served as house-surgeon and resident receiving-room officer at the London Hospital, and as assistant house-surgeon at the Poplar Hospital. In 1900 he returned to his native town of Burton-on-Trent, where his great-grandfather had been a founder of the brewing industry. There he entered partnership with the late Dr. Bridgman and he continued in the same practice, with Dr. W. P. Lowe and later with Dr. E. G. Frewer, until he retired in 1943.

Dr. Salt's whole interest centred in his large and busy practice. An ideal family doctor, kindly and cheerful, he never spared himself, and he endeared himself to a host of patients. A good general surgeon, his work at the Burton Infirmary, where he was appointed surgeon in 1902, was of a high order. His only recreation was golf, but he got little time for it except during his annual holiday, which he always spent in Scotland at his beloved Machrihanish.

He is survived by a widow and two married daughters.

Notes and News

CONVALESCENT HOMES

THE new edition of the King's Fund's invaluable directory[1] has *lost the original loose-leaf form, and is now a compact* and tidy volume bound in red and gold. It will be re-issued every spring, and so kept well up to date. Only homes willing to admit patients living in the London area are recorded, and those which lie outside the four Metropolitan hospital regions are grouped together in part II of the directory. Nearly all the homes which have remained outside the National Health Service, before being accepted for the directory, were visited by one or more members of the King's Fund convalescent homes committee. All the homes included are for patients for whom convalescence or a recuperative holiday has been recommended by a doctor. None of them is commercially managed.

HOSPITAL COSTS IN NEW ZEALAND

THE rising cost of hospital maintenance is reflected in the New Zealand Department of Health's account of expenditure by hospital boards in 1948.[2] In the years 1946, 1947, and 1948 the cost per occupied bed in general hospitals, by classes, was as follows:

Hospital (class)	*Cost per occupied bed (£)*		
	1946	*1947*	*1948*
I	421·8	460·7	556·6
II	424·9	447·7	503·2
III	364·4	442·2	516·9
IV	418·8	466·4	526·0

Class I hospitals have a daily average of over 200 occupied beds; class II, of 100–200 occupied beds; class III, of 40–100 occupied beds; and class IV, of 20–40 occupied beds.

In 1948 the average cost per occupied bed in hospitals with 10–20 beds occupied each day was £624·9; and in hospitals with 10 or less occupied beds, £631·0. For all general hospitals the average was £540·9. (The corresponding figures for special hospitals were as follows: infectious diseases, £569·6; tuberculosis, £343·0; and maternity, £559·5.) Of a total of 10,652 beds in general hospitals, an average of 8022 were occupied each day.

INSTITUTE OF PSYCHO-ANALYSIS

THE present building of this institute is too small for its teaching and clinical activities and its lease is near its end. Accordingly a new building has recently been purchased; but this cannot be ready for occupation for about a year, so any expansion of the work of the institute is not, at the moment, possible.

SIGHT-TESTING BY OPTICIANS

THE committee set up, under the chairmanship of Mr. William Penman, to investigate average times taken by opticians in connection with sight-testing and with *fitting* and supplying glasses under the Supplementary Ophthalmic Services, has now completed the first part[3] of its report. This shows that the average time taken by ophthalmic opticians to test sight is 36·16 minutes—an estimate which allows for such factors as writing letters to general practitioners, filling up forms, and losses due to broken appointments. Letters are written to general practitioners in about one-twelfth of the completed tests. "There is no evidence of widespread overwork. The two men who did most testing during the sample week made 69 and 56 tests respectively, the number of minutes actually occupied in sight-testing being 2162 and 1470 respectively." The average time per ophthalmic optician during the sample week was only 815 minutes; but "it has to be remembered that, whether a whole-time or a part-time ophthalmic *optician*, very few of the sample are engaged in sight testing alone in the Supplementary Ophthalmic Services. (The fitting and supplying of glasses is also their function.)"

"MEDICINE IN 1850"

AN illustrated catalogue is now ready of the exh (described in our issue of June 3) which is on show at Wellcome Historical Medical Museum, 28, Portman London, W.1, daily, except Sundays, from 10 A.M. to 5 The catalogue is published for the trustees of the mu by Geoffrey Cumberlege, Oxford University Press (pp. 64, and can be obtained through booksellers or from the publi but not by post from the museum.

THE PLAGUE IN LONDON

IN *Physician Extraordinary* Miss Shirley Murrell intro Sir Gilbert Blane to many who had never heard of him be In *Farewell Sweet Life*[1] she has given her imagination rein; at any rate the picture of Nat. Hodges, phys which she presents differs considerably from that given in *Dictionary of National Biography*. It is doubtful wh her variations have added interest to the doings of her h for anyone who—like the real Nathaniel Hodges, M.D. could choose a fire-engine as a suitable present for the Col of Physicians is surely a character ready made. The is set against the grim background of London in the d of the Plague.

MEDICAL POSTS IN SYRIA

EARLIER this year we announced[2] that the medical facul of the Syrian University, Damascus, had vacancies for Briti assistant professors of anæsthetics, anatomy, physiolog biochemistry, and histology and pathology. The physiolo and anatomy posts have now been filled, but there are possibl further vacancies for assistant professors of parasitology and bacteriology. Inquiries should be addressed to the Midd East Secretariat, Foreign Office, London, S.W.1.

TOOLS OF OUR ANCESTORS

IN a new book[3] on prehistoric tools, Mr. Kenneth P. Oakley adopts a conservative attitude about artefacts: he does n accept either Benjamin Harrison's eoliths or Reid M rostrocarinates, both of Tertiary age, as human handi Such stones, he says, "can be matched exactly by stones chipp by natural agencies"; but that is hardly a serious ans to the arguments elaborated by Reid Moir.[4] The old artefacts recognised as such by Mr. Oakley are the Oldow pebble tools found with a lower jaw of human type in an ear Quarternary deposit in East Africa. From that poi onwards he traces clearly the history of tool-making in stone, wood, and bone and correlates it with the successions of cultures. He shows that in early Palæolithic times in Europe there were two parallel cultures, of which one was charac-terised by Abbevillian and, later, Acheulian core-tools and the other by Clactonian and, later, Mousterian flake tools. The Abbevillian stone implements are regarded as derived from the Oldowan, and the Clactonian from the tools found asso-ciated with *Pithecanthropus pekinensis* in China. Most of the *later cultures derived from these* two main lines are described together with their interactions with one another, and thei relations with other human activities, such as hunting and ar Methods of making some of the tools are also indicated. A final diagram showing in parallel the cultures of Europe, As and Africa, suggests that the origin of them all is to be sought in Africa. A fascinating book.

University of Cambridge

On May 27 the following degrees were conferred:

M.D.—R. N. R. Grant, Vivien U. Lutwyche.
M.Chir.—H. E. Lockhart-Mummery.*
M.B., B.Chir.—Margaret M. Bates.

* By proxy.

Royal College of Physicians of Ireland

On June 2, the following were admitted to the fellowship:

M. L. Abrahamson, R. G. Cross, F. F. Kane, Simon Sevitt.

The following were admitted to the membership:

Dhirubhai Vallabhji Doshi, A. A. McG. McConnell, Ravind Vasant Rele, C. M. Sheridan.

North-East Metropolitan Region

The annual general meeting of the ophthalmologists i this regional area will take place at 6 P.M. on Thursday, June 22, in room 1301, 13, Portland Place, London, W.1.

nal University of Ireland

senate has decided to confer the honorary degree of on Sir Alexander Fleming, F.R.S.

dnought Seamen's Hospital, Greenwich

Stephen Power will demonstrate surgical cases at this tal at 3 P.M. on Thursday, June 29. The demonstration n to any doctor who cares to attend.

lwick Lecture

Tuesday, June 20, at 2.30 P.M., at the Royal Sanitary tute, 90, Buckingham Palace Road, London, S.W.1, Gordon M. Fair, dean of the Graduate School of neering of Harvard University, is to lecture on the neer in Public Health.

John's Hospital Dermatological Society

of. H. A. Harris will deliver the Prosser White oration is society at 1, Wimpole Street, London, W.1, on Thurs- June 22, at 4.30 P.M. A dinner will be held the same ing, and tickets (17*s.* 6*d.*) may be had from the hon. etary, *Dr. J. E. Schneider-Green, St. John's Hospital,* isle Street, W.C.2.

tish Cardiac Society

he 28th annual general meeting of this society was held the Westminster Hospital Medical School on May 25, ler the chairmanship of Sir Arnold Stott. At the morning sion, when there was a discussion on the use of anti- gulants with special reference to cardiac infarction and ipheral vascular disease, the opening speakers were Dr. Gilchrist, Sir James Learmonth, Dr. R. G. Macfarlane, d Dr. K. Shirley Smith. The short communications given the afternoon included papers on œsophageal lead electro- rdiography, tomographic and electrokymographic investi- tions of the heart, and the effect of drugs upon the venous d right ventricular pressures.

rvey of Growth

The Ministry of Health and Education are conducting, in njunction with the British Pædiatric Association, a survey the growth of infants and young children, with a view to mposing reliable growth charts. This survey, which began 1949, is being made in selected child-welfare centres; and e field work is being supervised, on behalf of the Ministry f Health, by Dr. Ethel Cassie. Data are being collected under e headings of growth, type of feeding, medical history, and ocial circumstances. In the first place about 20,000 babies, ll entering the survey below the age of two months, will be ncluded; the investigation will continue for at least three ears.

Extra Rations for Invalids

The Minister of Food announces changes in the arrangements for supplying extra rations to those suffering from diabetes and active tuberculosis. These changes, made with the agreement of the Rationing (Special Diets) Advisory Com- mittee of the Medical Research Council, are as follow:

Diabetes.—In addition to the ordinary rations of butter and margarine, diabetics may now obtain each week either (*a*) two extra rations of butter and one extra ration of margarine, or (*b*) two extra rations of margarine and one extra ration of butter. (Margarine may still be taken in place of all, or part, of the butter entitlement.) At [illegible] and margarine combined ent[illegible] They will continue to be [illegible] rations and the special cheese ration of 12 oz.

Active Tuberculosis.—People suffering from active tuberculosis will in future be entitled to obtain each week one extra ration of butter or margarine instead of the following extra allowances: 3 oz. butter or margarine, 1 oz. cooking fat, and 1 oz. bacon. The extra allowances of cooking fat and bacon were granted at a time when the ordinary rations of these two foods were 1 oz. and 2 oz. respectively. The present rations of cooking fat and bacon are 2 oz. and 4 oz.

Canned Milk and Proprietary Infant Milk Foods.—Since these are no longer controlled, the special arrangements for making supplies available to certain infants and invalids have lapsed.

Dried Banana Flakes.—Patients suffering from steatorrhœa, cœliac disease, or tropical sprue will in future be able to obtain dried banana flakes as well as dried bananas.

Priority Milk and Eggs.—Now that milk-supplies are unrestricted and eggs more plentiful, medical certificates are not needed to enable invalids to obtain priority supplies. In some cases, however, authority for foods other than milk is granted against a milk code-number.

Award for Research on Infertility

The American Society for the Study of Sterility offers an annual award of $1000, known as the Ortho award. The competition is open to those in clinical practice as well as those whose work is restricted to research in the basic sciences. Essays submitted for the 1951 contest must be received not later than March 1. Further particulars may be had from the society, 20, Magnolia Terrace, Springfield, Mass.

Church of England Hospital Chaplains' Fellowship

The annual conference of this fellowship, held in London on May 24 and 25, expressed opposition to both "mercy-killing" and euthanasia. On leucotomy it was felt that knowledge was still insufficient for moral judgment. The conference agreed that normally it was desirable for any dying patient who was a practising Christian to be told of his approaching death.

Research Board for the Correlation of Medical Science and Physical Education

On Tuesday, June 20, at 2.30 P.M., a meeting of this board will be held at Apothecaries' Hall, Black Friars Lane, London, E.C.4, when it is hoped that Mr. George Tomlinson (Minister of Education), Lord Webb-Johnson, and Miss L. E. Charlesworth will discuss medical science and physical education from the educational, medical, and international points of view respectively.

Sickness Benefit

The first report of the Ministry of National Insurance, covering the period from Nov. 17, 1944, when the Ministry was created, to July 4, 1949, shows that during 1948–49—the first year of operation of the new National Insurance scheme—some 39 million sickness-benefit payments were made. New claims totalled 7 million—an average of 140,000 a week. The number of people receiving sickness benefit was at one time 1,100,000; but by midsummer, 1949, the number had dropped to 800,000.

West London Medico-Chirurgical Society

Proposing the health of this society, at its annual dinner held at the Royal College of Surgeons on June 2, Sir Cecil Wakeley, P.R.C.S., spoke of the West London Hospital's 95 years' history of "triumph upon triumph." In their discussions doctors were apt to overdo the subject of the moment; but the society did more than bring the general practitioner and the consultant together, and he saw great value in its dinner meetings to which members could bring their wives. He was glad that it should make use of the college for its annual dinner: "what we want in every branch of medicine is cooperation." Mr. V. B. Green-Armytage, replying as president, said that the society had been founded in 1884 for the mutual benefit of practitioners and consultants and had reached its zenith with a membership of 608. Today, possibly because of the effect of the National Health Service on general practice, the number was only 258: the practitioner, he feared, had no longer any inclination to go out to dinner. All doctors were from the same mould (though it had been said that some were mouldier than others), and he was thankful that new hope had dawned for the G.P. in the B.M.A. report on training for general practice. Meanwhile the society's monthly meetings continued to be successful and a record audience had attended the Cavendish lecture by Lord Mountevans. Dr. W. S. C. Copeman, proposing the Guests, recalled a previous Cavendish lecture by Lord Dawson, which had led directly to the Dawson report of 1920. Pigeon-holed till 1947, this report had been brought out in the form of the National Health Service, for which the society could therefore take any credit obtainable. Lord Mountevans, Sir Neil Cantlie, and Prof. Hans Selye responded. Lord Mountevans began and ended with Robert Louis Stevenson ("the sailor's poet"), touching meanwhile on Cheatle forceps, asparagus, and other congenial topics. General Cantlie expressed his regret that young doctors should imagine that 18 months' Army service would be clinically a waste of time: in peace-time the R.A.M.C. looked after 400,000 people, 5000 children were born in Army families' hospitals each year, and 7000 operations were performed in Army hospitals, which were now open to civilians. Professor Selye, as the last speaker, diverted attention to the more local (but occasionally urgent) problem of getting decomposable pathological specimens across the customs barrier between the United States and Canada.

Medical Week at Verona

An international medical week is to be held at Verona from July 20 to 30. Further particulars may be had from Prof. Luigi Barchi, Pescheria Vecchia 6, Verona, Italy.

Last month Dr. Macdonald Critchley, as a visiting professor in neurology to the University of Istambul, gave a series of lectures in Turkey. He also delivered lectures in Athens and in Ankara under the auspices of the British Council.

France, Italy, Austria, Denmark, and Syria are being represented at a British Council course on British Health Services Today which is being held in Cardiff during the first fortnight of June.

Appointments

BAILEY, BERYL, M.B. Lpool: temporary asst. M.O. in maternity and child welfare, Birmingham.
COLLINS, E. G., M.B. Edin., F.R.C.S.E.: senior ear, nose, and throat surgeon, Aberdeen general and special hospitals.
CORALL, J. M., M.B. Aberd., D.M.R.: consultant radiologist, Medway and Gravesend and Mid-Kent hospitals groups.
JOHNSON, S. J., M.B. Lond., D.M.R.D.: consultant radiologist, Canterbury and Isle of Thanet hospital groups.
KIRBY, N. G., M.B. Birm.: surgical officer (B1), Stoke Mandeville Hospital, Bucks.
LENDON, N. C., M.A., M.B. Camb., D.P.H.: M.O. (B1), Queen Alexandra Hospital, Cosham, Hants.
LINACRE, J. L., M.B., M.SC. Sheff., D.A.: consultant anæsthetist, Eastbourne hospitals group.
NELSON, D. H., M.R.C.S., D.M.R.D.: consultant radiologist, South-East Kent hospitals group.
RAINER, E. H., L.R.C.P.E., F.R.C.S.E.: consultant ear, nose, and throat surgeon, Dartford and Sidcup and Swanley hospitals groups.
REID, J. L., B.M. Oxfd, F.R.C.S., D.L.O.: consultant ear, nose, and throat surgeon, Canterbury, Isle of Thanet, and South-East Kent hospitals groups.
SMITHAM, J. H., M.B. Lond., D.M.R.E., F.F.R.: consultant radiologist, Lewisham hospitals group.
TERRY, S. W. W., M.B. Madras, D.T.M. & H., D.P.H.: asst. M.O.H. and school M.O., Bristol.
THORNTON, MAIRE, M.B. N.U.I.: temporary asst. M.O. in maternity and child welfare, Birmingham.

Births, Marriages, and Deaths

BIRTHS

CATHRO.—On May 28, the wife of Dr. A. J. M. Cathro—a son.
CHRISTIE.—On May 24, in London, the wife of Dr. H. D. Christie—a daughter.
COIGLEY.—On May 23, at Kinrara, Kuala Lumpur, the wife of Captain M. H. F. Coigley, R.A.M.C.—a daughter.
COTES.—On May 31, in London, the wife of Dr. John Cotes—a son.
FOSTER-CARTER.—On May 25, in London, the wife of Dr. A. F. Foster-Carter—a daughter.
HAMILTON.—On May 22, in London, the wife of Dr. Henry C. Hamilton—a daughter.
HANLEY.—On May 25, in London, the wife of Dr. Thomas Hanley—a son.
HEARN.—On May 29, in Birmingham, the wife of Dr. G. W. Hearn—a daughter.
LOVELL.—On May 29, in London, the wife of Dr. R. R. H. Lovell—a daughter.
MACDOUGALL.—On May 28, at Teddington, the wife of Dr. George Macdougall—a daughter.
OSWALD.—On May 26, in London, the wife of Dr. Neville Oswald—a daughter.
REID.—On May 26, at Henley-on-Thames, the wife of Dr. R. O. D. Reid—a daughter.
WOLFSON.—On May 26, in Birmingham, the wife of Dr. L. J. Wolfson—a daughter.
WOODS.—On May 30, in London, the wife of Dr. Arnold Woods—a son.

MARRIAGES

LACY—MILLAR.—On May 20, at Bolton, Peter Broadhead Lacy, M.B., to Winifred Joan Millar, M.B.

DEATHS

BELFRAGE.—On May 31, at Penn, Bucks, Sydney Henning Belfrage, M.D. Lond., aged 78.
CARVER.—On May 30, Alfred Edward Arthur Carver, M.A., M.D. Camb., D.P.M., D.P.H.
GUY.—On May 28, in Edinburgh, William Guy, F.R.C.S.E., F.D.S.R.C.S., F.R.S.E., LL.D. Penn., aged 90.
HOLMES.—On May 26, at St. Annes-on-Sea, Francis Bernard Greame Holmes.
LEWIS.—On May 26, Harold Warburton Lewis, M.B. Lond.
MACKENZIE.—On June 3, at Chalfont St. Giles, Donald Francis Mackenzie, D.S.O., M.B. Edin., colonel, late R.A.M.C. retd, aged 69.
PORTER.—On June 4, at Faversham, Kent, Herdman Porter, M.B. Edin., aged 74.
POTTS.—On May 25, at Great Yarmouth, Horace Potts, M.R.C.S., aged 79.

Diary of the Week

JUNE 11 TO 17

Monday, 12th

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.1
5 P.M. Dr. Desmond Curran: Toxic Confusional Psychoses.

Tuesday, 13th

ROYAL COLLEGE OF PHYSICIANS
5 P.M. Dr. E. R. Cullinan: Diseases of the Liver. (5 lecture.)
INSTITUTE OF DERMATOLOGY, Lisle Street, W.C.2
5 P.M. Dr. E. J. Moynahan: Collagen.
INSTITUTE OF NEUROLOGY, National Hospital, Queen S W.C.1
5 P.M. Dr. Marcel David (Paris): Technique et une métho reparage des structures souscorticales. (Film.)
INSTITUTE OF OPHTHALMOLOGY, Judd Street, W.C.1
5.30 P.M. Sir Stewart Duke-Elder: Glaucoma.
NATIONAL HEART HOSPITAL
5 P.M. (1, Wimpole Street, W.1.) Dr. Paul Wood: Conge Heart-disease. (St. Cyres lecture.)
PADDINGTON MEDICAL SOCIETY
8.45 P.M. (St. Mary's Hospital, W.2.) Dr. W. D. W. Brook Hypertension.
MIDDLESEX COUNTY MEDICAL SOCIETY
3 P.M. (North Middlesex Hospital, Edmonton.) Clinical a pathological demonstrations. Mr. Hedley Hall: Revie of 1000 Laminectomies for Prolapsed Intervertebr Disc.
EDINBURGH POST-GRADUATE BOARD FOR MEDICINE
5 P.M. (University New Buildings, Teviot Place.) Dr. J. Scadding: Bronchial Obstruction.

Wednesday, 14th

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2
5 P.M. Prof. Leon Stone (Yale University): Developme of Normal and Reversed Vision in Transplanted Eyes.
UNIVERSITY COLLEGE, Gower Street, W.C.1
5 P.M. Prof. Sewall Wright, SC.D. (Chicago): *Genetical Structur of Populations.* (Galton lecture.)
INSTITUTE OF DERMATOLOGY
5 P.M. Dr. H. Haber: Histology.

Thursday, 15th

ROYAL COLLEGE OF PHYSICIANS
5 P.M. Dr. Emanuel Miller: Some relations of Child Psychia to Pædiatrics.
ROYAL COLLEGE OF SURGEONS
5 P.M. Dr. S. A. Henry: Cutaneous Cancer in relation t Occupation. (Hunterian lecture.)
INSTITUTE OF OPHTHALMOLOGY
5.30 P.M. *Professor Stone:* Experimental Studies on the Eye Based upon Regeneration of the Neural retina and th Lens.
ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, S.W.1
4.30 P.M. Dr. Mallinson: Psychiatry lecture-*demonstration.*
ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 26, *Portland* Place, W.1.
7.30 P.M. Dr. Frank Hawking: Filariasis.
HONYMAN GILLESPIE LECTURE
5 P.M. (University New Buildings, Teviot Place, Edinburgh Mr. Bruce Dick: Bronchial Adenoma.

Friday, 16th

ROYAL COLLEGE OF PHYSICIANS
5 P.M. Dr. F. H. Young: Use of Collapse Therapy in the Tr ment of Pulmonary Tuberculosis. (First lecture.)
MEDICAL RESEARCH COUNCIL
5.15 P.M. (London School of Hygiene, Keppel Street, W.C. Prof. A. C. Burton, PH.D. (University of Western Ontario Clothing and Heat Exchanges in the *Human Body.*
MAIDA VALE HOSPITAL MEDICAL SCHOOL, W.9
5 P.M. Dr. Anthony Feiling: Clinical neurological dem stration.
CONFERENCE ON INFERTILITY
10 A.M. (House of the Zoological Society, Regent's P London, N.W.) Mr. Kenneth Walker: Diagnosis Treatment of Male Infertility. Dr. R. G. Harrison, A. G. Oettlé: Pathological Changes in the Rat Te following Ischæmia.

Saturday, 17th

CONFERENCE ON FERTILITY
10 A.M. Mr. Samuel Siegler, F.R.C.S.: *Reflections upon* S Aspects of Fertility, and Film on Sterility. Mr. I. Rowlands, PH.D.: *Breeding of Dogs.* Dr. Marga Hadley Jackson: Significance of Round-cell Infiltrat as Seen in Endometrial Biopsy Sections.
2 P.M. Dr. Claude Béclère: Hysterosalpingography in Diagnosis and Treatment of Sterility. Mr. A. Walt PH.D.: Activity of Spermatozoa in vitro. Dr. Het Solomons: Some Conclusions about Infertility.
BIOCHEMICAL SOCIETY
11 A.M. (School of Biochemistry, Cambridge.) Short paper

WEAR AND TEAR *

LORD MORAN
M.C., M.D. Lond., F.R.C.P.
ONSULTING PHYSICIAN TO ST. MARY'S HOSPITAL, LONDON

I HAVE chosen "Wear and Tear" as my title, because want to be at liberty to dip into the underworld of edicine where aberrations of the mind are found. In ngland, medical students are sometimes poorly schooled these matters, and I am under the impression that ysicians, broadly speaking, are obsessed with the ientific approach to medicine. We have forgotten the reek saying that a doctor has opportunities of studying uman nature which are given to no-one else, wherefore philosopher ought to begin his life as a doctor, and a octor should end his life by becoming a philosopher.

I must begin by a search for physical evidence of wear nd tear; and I have to admit at the outset that the tresses and strains of everyday life on individual organs re difficult to assess, because we have only a vague nowledge of their functional reserves. Just where we might expect the fret of life to leave its mark—on the irculation—we find little that is tangible. James Mackenzie said that he had never seen a strained heart, and Thomas Lewis affirmed that the circulatory organs were built to stand the strains which they themselves create. While Abrahams, working with a competent radiologist, found that the heart of the athlete appears to be smaller, not bigger, than the average for his height and build.

The response of elastic tissue is another story. The signs of wear and tear are obvious, for any distensible organ when subject to prolonged strain loses its elasticity. The lungs of a patient with chronic bronchitis become emphysematous, the blood-vessels suffer in hypertension, the bladder in chronic urinary distension does not escape.

If we include in a record of wear and tear changes in the suprarenal gland in response to alarm stimuli which are transient and in the nature of physiological responses, it seems reasonable to refer to the effect of emotion in inhibiting the peristaltic movements and secretion of the gastro-intestinal tract. Thirty years ago, when I was working in Bickel's laboratory in Berlin, there was a dog by my bench with a Pavlov stomach. It was eating some meat contentedly so that I could see the gastric juice flowing freely. Then the door opened and a cat was brought in. The dog leaped forward until restrained by his chain; the secretion of gastric juice ceased. Since that time many observers have recorded the effect of emotion on peristalsis and on secretion. For my part, when I look back on those thirty turbulent years, and on the inhibitions I must have suffered, I find myself asking, is there no scar left, no structural trace of those agitated interruptions? But I must end my search for objective evidence by reminding you that the onset of diabetes and of hyperthyroidism may be associated with an emotional disturbance.

THE MIND IN WAR

Even an untutored eye can detect the imprint of pain and hard usage on a friend's face, and yet my search for physical signs of wear and tear has not been very productive. But when I turn away from the body and ask what is the effect of prolonged stress on the mind, I can quote a classical experiment which is pat to my purpose. The severity of the strain to which a battalion was subjected in France in the first world war was, I think, greater than anything the infantry experienced during the last war. For in the winter of 1914 the men were standing in waterlogged trenches, shelled by the Germans, without ammunition to reply, while later the long-drawn-out ordeal of trench warfare was punctuated by massacres, such as the battle of the Somme.

I became interested in the manner in which the men responded to this stress in the following manner. I was medical officer to the 1st Royal Fusiliers in France. One day in 1914, at Armentières, when we were waiting to go up to the trenches to relieve a battalion, word was brought to me that there was a sergeant in his billet who was not well. I asked him what was wrong. He said "nothing—he was all right." He was a morose fellow and I could get nothing out of him. I examined him carefully but found nothing. He did not appear to be ill. I told him he could stay in his billet until the battalion came out of the trenches. But when we had gone, he blew his head off. This man was not afraid to die, but he had found he could not face war and was uncertain what he might do, and had taken the matter into his own hands before he did something dreadful that might bring disgrace on himself and on the regiment. I had a feeling that I had been responsible for this fellow's end, that he should have been sent down the line sick. I began to ask: what was happening in men's minds? How were they wearing? For four years I tried to find answers to those questions, which are of everlasting consequence in war.

From the autumn of 1914 until the spring of 1917 I was with the 1st Royal Fusiliers, a fine battalion of a famous regiment, and I have recorded, the results of my long vigil in a short chapter of *The Anatomy of Courage*, that I called The Birth of Fear. In retrospect I am delighted by the poverty of my description of the signs of wear and tear in that battalion. During the battle of the Somme there were no sick, none would ask for an easy ticket to the rear. But if little was found I do not think much was missed. I was with one of the companies during the Somme battle, went with the men on raids, and lived with them. In short, what I have said in their praise I saw with my own eyes. What was found on the debit side?

Once, I remember, a subaltern developed a facial tic. Yet he did his job, and as the months went by without anything happening my doubts were gradually lulled to rest. But after the Somme there seemed to be a change in him. He began to get irritable at some little thing, sometimes even at nothing, and then one day he was found in an epileptic fit. And I remember another young officer, a gay, carefree boy, but one night I shared a dugout with him and was roused from my sleep by his shouts and yells. I went to wake him from his dreams: then, with my hand on his shoulder I stopped. He would not wish to share his secret with anyone. A week later he was killed.

The absence of obvious signs of wear and tear in this battalion during that time is in striking contrast to my experience in the autumn of 1917 when I was sent to Boulogne to find out how the wastage from mustard gas could be checked. With James Mackintosh I published in the *Quarterly Journal of Medicine* an analysis of a consecutive series of 1500 mustard-gas casualties admitted to No. 7 Stationary Hospital between Jan. 1 and Oct. 31, 1918. There was a mortality of 2%; on the other hand, we found that 87% of the men could march half a mile to a convalescent camp in their equipment within a month of gassing. In them the organic lesions were negligible or absent, it was the mind that had suffered hurt.

> "Gas, after July 1917, partly usurped the rôle of high explosive shell in bringing to a head a natural unfitness for war, or less frequently a fitness sapped by exceptional stress of experience in the field. In many cases where the signs of gassing cleared up in a few days, we had to deal with a

---

* Based on an address to the American College of Physicians on April 17.

condition of mild gas shock, comparable to the slighter cases of shell shock which reach a Casualty Clearing Station after an action. This condition, with its accompanying functional nervous disorders, was an expression of trench fatigue."

There were 113,000 casualties from mustard gas, and, if our investigations were a fair sample, nearly a quarter exhibited a functional nervous disorder which reacted promptly to suitable treatment. We found every kind of manifestation of hysteria, from hemiplegia to hysterical aphonia. (In our series there were 108 cases of hysterical aphonia.) What was the explanation of the disparity between the behaviour of these misfits in war and of the men of the Royal Fusiliers? The men in that battalion were in a sense picked men. They had joined the Army in time of peace partly from a sense of adventure, rather than spend their lives in an office; they were not security-minded. And they were fortified too by a regimental spirit, an esprit-de-corps, to which I testify in my little book, which is their epitaph. The majority of the men who left the front line in 1917 "gassed" were frankly frightened. They were the military rubbish, which is found in every democracy. Incidentally, in the Royal Air Force in the last war it was found that in two-thirds of the pilots who broke down there was evidence of a flaw which was inborn: the way a man is made matters more than the risks he runs.

THE NATURE OF NERVOUS FATIGUE IN WAR

Watching for the signs of wear and tear through all those months, it was perhaps inevitable that one came to ask—could nothing be done to fortify these men to meet strain; and what was the nature of this nervous fatigue and how was it caused? In the Royal Air Force the mental strain of flying, Symonds has said, is precisely in proportion to the danger. Where the danger was greatest, as in Bomber Command, there the number of pilots who broke down was also greatest. It is not however quite accurate to say that the strain is in proportion to the danger, for if a man's threshold to fear is high, he may go through hazards with impunity; while if he is easily frightened, he may break down when the danger is of no consequence. The Greeks knew this, for Aristotle said that fear is the normal response to the instinct of self-preservation to danger and that it only becomes morbid when it is out of proportion to the degree of the danger. It would be more just to say that the fear of flying is a measure of the strain. Put differently, it is the long-drawn-out control of a persistent state of fear which ends in a pilot's defeat. In the history of the English Army, the threshold of fear has been gradually falling. Five centuries ago Shakespeare said of our men at Agincourt, "If these English had any apprehension they would run away." The strength of those yokel soldiers lay in their vacant minds; they did not stop to measure their chances of survival. And then the centuries passed, and, as these men became civilised and more open to impressions, their threshold to fear fell, until Thomas Hardy wrote of the soldier of our time: "More life may trickle out of a man through thought than through a gaping wound."

It is not true of course that all men with a high threshold of fear have vacant minds. I remember after the last war receiving an invitation to lecture to the Staff College of the Royal Air Force. I found about 140 pilots gathered in a hall, the pick of the survivors of the war; every man seemed to possess the decorations which the discriminating value, and I recall a sense of incongruity that I, an elderly apothecary, should have to admonish these men on morale. I invited them to answer a *questionnaire*, to put on paper in the order of their importance the qualities which in their experience make a good pilot in war. Their assessment is, I believe, worth recording on account of their unique authority in this particular field.

1. Calmness: in their jargon, the man who does not flap.
2. Determination: the man who does not give up easily.
3. Dependability: the pilot who can be relied on to do a thorough job.
4. Discipline: willingness to carry out orders.
5. Keenness.
6. Aggressiveness: the hallmark of the "ace" pilot.
7. Confidence.
8. Decisiveness: the ability to make up the mind quickly.
9. Initiative: resource, the ability to cope with new conditions.
10. Coöperation: working harmoniously with a crew.
11. Influence: respect.
12. Sense of humour: ability to laugh at oneself.
13. Appearance and bearing. Smartness.
14. Power of self-expression.
15. A good mixer.
16. Breadth of outlook. Wide interests.

Every command represented there gave their vote for the personal attributes which bring success in air operations, while at the bottom of the list, huddled together, are the qualities which we have come to associate with worldly advancement—further confirmation, if it were needed, that success in war and success in peace are not necessarily due to the same qualities. A sense of humour comes out poorly, though the Day Fighters supported it. The Night Fighter was the strongest advocate of the value of confidence. In brief these men were not security-minded, and their attitude to life seemed to raise their threshold to fear.

While the threshold to fear has steadily fallen through the centuries, sapped by the spread of education and the stirring of the imagination, there has been what Wilfred Trotter would have called a biological drift to stiffen the citizen for the ordeal by battle. Trotter, in some of his most persuasive and eloquent pages, records a growing tendency to accept selfishness as a test of sin, and consideration for others as a test of virtue. He affirms that throughout the incalculable ages of man's existence as a social animal, nature has been hinting to him in less and less ambiguous terms that altruism must become the ultimate sanction of his moral code, the supreme moral law. The historian may decide that the democracies, confronted by the menace of the fanaticism of Germany and Japan, were saved by altruism, which Trotter defined as the capacity to make the interests of another individual one's own. The physician is more concerned with finding a physical basis for those signs of wear and tear which I have described as the consequence of the secret battle between fear, or the instinct of self-preservation, on the one hand, and control, or will-power, or courage, or whatever you like to call it, on the other.

WHAT HAPPENS IN THE BODY AS THE RESULT OF THIS MENTAL CONFLICT

There is no sign of any lesion in the central nervous system. Is there any evidence connecting the suprarenal gland with this nervous fatigue? Some careful workers in England have been doubtful whether there is any proof as yet of the involvement of the adrenal gland. They argue that the reports that fatigue and stress were accompanied by increased loss of ketosteroids in the urine were backed by figures which are not outside the range of possible error of the method of estimation. They say again that parallel experiments by the Royal Air Force, during and since the war, have failed to confirm these figures; while to give a man Compound E does not help him to resist stress.

But apart from Pincus's highly suggestive work, if there is no direct proof, there is much circumstantial evidence supporting Selye's hypothesis. It provides an explanation for things which have been inexplicable. I all give a personal experience as an illustration. Once twice a year, when I have been aggressively attacked debate, I have experienced a sharp pain in the small my back lasting, perhaps, thirty seconds. I ascribed is pain to muscular spasm until one day I was having tooth stopped. I was not in pain and I was thinking other things with my eyes closed when suddenly I lt this familiar pain in my back. "What are you oing?" I asked, opening my eyes. And the dentist nswered that he was injecting adrenaline. Half an our later, when I had forgotten the incident, I had the ame pain again and found that he was again injecting drenaline.

Since my return from America, Dr. Peter Bishop has een kind enough to send me an account of a similar ersonal experience. He writes:

> "I had a curious experience two or three days ago in which I think you may be interested. I was driving home to Harpenden, where I live, and the roads were wet. Suddenly I ran into a skid which I controlled only within 100 yards, nearly having picked off a cyclist in the meantime. Once I was in control of the car again I sat back relaxed and relieved. I then began to realise that I was suffering from an acute pain which I eventually located bilaterally in the costophrenic angles. I suppose this must have been due to congestion of my adrenals as the result of Selye's alarm reaction, possibly induced, as you suggested, by release of adrenaline."

Again I need not remind those who are familiar with the behaviour of the eosinophils after alarm stimuli that the experienced physician who used to follow the course of pneumonia by taking daily blood-counts knew that the patient had turned the corner when the eosinophils reappeared in the blood.

Incidentally I find that the description of the behaviour of soldiers under stress, which I described in 1914—35 years ago—bears an interesting resemblance to the language in which Selye describes his adaptation syndrome. I spoke of the exhaustion of will-power: he speaks of the exhaustion of nervous energy reserve. I said that in a battle "somehow the horror of this business of war was not felt. Nature has the stop on: we must be half doped to come through it at all." Selye calls it—"the mental stupor of the shock stage."

Again, we speak now of the euphoric condition after an alarm stimulus, which we ascribe to the increased output of adrenal steroids. Thirty-five years ago I described a similar emotion when I heard my first shell. It came into the room of a farmhouse, in front of Armentières, when we were lying in reserve, two hundred yards from the Germans, and it killed three men and wounded five others. When I had got the wounded away I ate heartily and I remember being filled with compunction that I could be so callous. On that day, Dec. 20, 1914, I wrote in my diary—"And, in spite of the three dead men, I could not help feeling cheerful now that it was over. It was as if I had achieved something, though I had done nothing."

Nor can I claim to be the first to paint a clinical picture of the symptoms and signs that may follow alarums and *excursions*. Caesar said that he could make a man a coward by starving him for three days. That was a good many centuries before Selye found in rats that fasting is particularly effective in increasing their sensitivity to alarm stimuli.

We may then say that if the relationship of Selye's adaptation syndrome to any disease occurring in man has yet to be proved, he has demonstrated that delayed reactions to trauma may occur in the bodies of animals, clearly showing that those reactions are related to activity of the adrenal cortex. Though histological changes in the central nervous system and endocrine glands have never been demonstrated in man, it seems probable that there is in him a corresponding pituitary-adrenal response to alarm stimuli. But the effects are transient and ought to be regarded as physiological reactions rather than lesions. There is evidence of overactive autonomic response, and the disorder may be said to lie in the borderland between normal and abnormal vegetative function. Selye has then made an interesting contribution to scientific thought, and his concept has given an experimental background to psychosomatic medicine.

* * *

My final reflections are of a more general nature, underlining the danger of dogmatism in the field of science. I am thinking of a man of repute in the scientific hierarchy who scoffed contemptuously when told that a woman with rheumatoid arthritis had received miraculous relief from a visit to Lourdes. We can understand now how an intense psychological stimulus may have led to an increase of the adrenal steroids in the blood, so that within six hours this woman felt better and her joints became more mobile. Perhaps she was so elated by the improvement in her condition that she received another stimulus which continued the improvement, and she had probably left Lourdes before she relapsed. It was said of Frederick Taylor that at the end of his life he was so conscious of the possibility of error that he never ventured to make a diagnosis. Certainly as we grow older we come to see that all knowledge is provisional.

And on that note of caution I shall bring to an end these discursive remarks. For even if it is proved, as I believe it will be proved, that in man under stress there is a suprarenal reaction, it is doubtful whether this will lead to any helpful action in fortifying him to meet the strain. We may at the most be able to stiffen his resistance for a few hours, but he will have to pay for it later. Nor can man's behaviour under stress be explained away by any endocrine response. A man with Addison's disease living in adrenal poverty, will often behave with great courage, taking no thought of the fact that a slight infection might be fatal. The truth is we do not yet possess any physical explanation of man's behaviour when under stress.

INFLUENZA: A STUDY IN MICE *

S. Fazekas de St. Groth
M.D. Budapest, Sc.M.

From the Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia

Over the past two years research in our laboratory has been focused on the factors governing susceptibility and resistance to experimental influenza. I try to give here a coherent picture of the pathogenesis and immunogenesis of influenza emerging from these studies.

The broader approach adopted involves inevitably much repetition, since the recently developed and improved techniques had to be applied to *all* the problems. As a result, many of our findings are not more than a restatement in quantitative terms of earlier observations. However, they help in viewing the integrant processes in their true context, and provide a background against which the novel facts and concepts can be assessed.

Some justification is needed perhaps for our choice of experimental animal. Although influenza is not a natural disease of the mouse, most human strains of virus can be adapted without difficulty to this host. Experimental infection with such strains closely parallels the human condition, the differences being quantitative rather than qualitative. Use of the mouse as a *model* therefore, allows extensive studies into the essential pathological and immunological processes, which could not be made readily in the natural host.

---

* Substance of a lecture in the series "Methods of Biological Research," given on Feb. 25, 1950, in the University of Melbourne. The work was aided by a grant from the National Health and Medical Research Council, Canberra, Australia.

INITIATION OF INFECTION

Influenza viruses are specifically adsorbed to certain cells, among others to those in which they can multiply. That part of the cell membrane with which the virus combines is called the *receptor*. The virus carries embedded in its surface an enzyme capable of acting on the receptor ("destroying it") and thus releasing the virus from the cell surface. These facts, firmly established on non-living cells, led to the somewhat hasty conclusion that (1) in the virus-cell combination it is the viral enzyme that combines with its substrate, and (2) destruction of the enzymic receptor is necessary for infection—indeed, it is *the* mechanism by which the virus forces its way into the future host-cell (Hirst 1942, 1943, 1948).

This hypothesis had to be discarded because it does not fit the facts. The virus-cell combination is not simply an enzyme-substrate interaction, because (1) enzymically inactive (heated) virus is still adsorbed by cells (Hirst 1942, Briody 1948), (2) cells containing modified substrate on which the enzyme cannot act still bind virus, and (3) cells without substrate combine with virus lacking enzyme action (Fazekas de St. Groth 1949). That the enzymic destruction of receptors is not essential for infection is evident from experiments where cells were as readily infected by virus whether or not their receptors contained destructible substrate (Fazekas de St. Groth and Graham 1949).

What, then, is the mechanism by which the virus enters a host-cell if the action of its enzyme is of no avail in this process? The experiments gave an unequivocal answer: virus, dead or alive, once adsorbed to the surface of living susceptible cells, is *ingested by the cell*. Whether or not the receptors involved contain substrate is irrelevant, as is the fact whether the viral enzyme was active or not during the process (Fazekas de St. Groth 1948c). This process by which the cell takes up virus was termed *viropexis* (by analogy to colloidopexis, the passive uptake by cells of adsorbed submicroscopical particles).

Hence the initiation of infection by influenza virus involves two major steps: (1) physical adsorption between two complementary surfaces of colloid dimensions (the virus particle and the cellular "receptor area")—something like an antigen-antibody combination—and (2) ingestion of the adsorbed virus by cell (viropexis)—something like phagocytosis.

COURSE OF DISEASE

Once inside a host-cell, the virus is beyond our re All we can do is to look for the net changes in the infec tissue and guess what has happened in individual cells. There is no shortage of such speculations; relevant facts are less abundant.

We tried to approach the problem from as many sides as possible, and the investigation consisted essentially in daily determinations in infected mice of the *virus* content of ground lung tissue and of bronchial washings; of soluble *complement-fixing antigen* (distinct from the virus, of smaller size and non-infective) in lungs and in the air-passages; of the number of available *receptors* in the respiratory tract; and of the amount of virus *inhibitor* contained in respiratory secretions. Further, the two types of specific *antibody* (one against the virus the other against the soluble complement-fixing antigen) were titrated in sera and in bronchial washings. The composite picture so obtained was correlated with the macroscopical *lesions* of the lungs, and the *histopathology* of the disease was followed. The whole of the process may be outlined as follows.

Practically all of the infective inoculum is taken up by cells, and no virus can be detected during the "lag period" by any known method. The soluble complement-fixing antigen appears then in the cells, followed closely by the liberation of infective virus into the air passages. (The soluble complement-fixing antigen is not released from the cells in significant amounts.)

Fresh cells are not infected at random; there is good evidence that the normal spread trends upwards—i.e., follows the physiological movement of the respiratory mucus. Straub (1940) and Taylor (1941) have observed already that an innocuous nasal inoculum—e.g., normal saline—given to mice infected a few days previously with sublethal doses of influenza virus will precipitate the disease, cause the virus content of the lungs to rise several hundredfold, and kill all the mice with complete pulmonary consolidation. We found that in sublethally infected mice the number of available receptors did not drop to the same extent as in lethal infections (Fazekas de St. Groth 1950a), and that less complement-fixing antigen was produced (Fazekas de St. Groth and Donnelley 1950a), all this pointing to a smaller number of cells being involved. The simplest explanation of these facts is to suppose that peripheral cells which escaped infection with the primary inoculum

TABLE I—DIAGNOSIS OF INFLUENZA IN MICE
(Challenging virus: Melbourne (A) strain)

Laboratory Tests (applicable over periods shown in parentheses)		Normal mice									Immune mice *

} difference from pre-infection level.

l not be exposed to virus infection at a later stage. e newly formed infective particles released from the re central cells will be carried by the sheet of respira-y mucus, known to adsorb influenza viruses (Fazekas St. Groth 1948a and b), and will infect still intact ls on their way out. This interpretation also explains o other regular findings: (1) the substrate in respira-ry secretions is "destroyed" as soon as the virus has ished its first growth-cycle, and (2) large amounts of rus are excreted via the trachea, even if there are illions of infectible cells in the peripheral ramifications the respiratory tree.

The severity of the disease is apparently governed by e number of virus particles that have been produced. nd thus depends on two main factors: the size of the fective inoculum, and the intrinsic multiplication-rate f the virus.

Unlike the growth of virus in eggs, infection of a ammalian host is something like a race. It is not erminated by the exhaustion of infectible cells but by he appearance of antibody. And here we are faced with an intricate problem. Detectable antibody appears n the circulation about the seventh day (between days 5 and 8). However, it is difficult not to suspect that antibody was *produced* from the third day. There is strong though indirect evidence for this assumption. In mice vaccinated with killed virus either by the peritoneal or the nasal route antibody appears regularly between days 3 and 5. If live virus is given by any extrarespiratory route, antibody again appears on day 3. If the same amount of live virus is given nasally (experimental infection), the serum titre starts to rise only on day 7. Yet the infected lungs become anticomplementary from day 3 onwards, and this is due to an antigen-antibody complex (Fazekas de St. Groth and Donnelley 1950b). At the same time a conspicuous plasma-cellular reaction is observable both in the regional lymph-nodes and in the peribronchial connective tissue (Bate 1950, Bate et al. 1950), a phenomenon increasingly accepted as the morphological manifestation of antibody production.

It may therefore be concluded tentatively that antibody production *does* start at the same time in an infected as in a vaccinated animal, but that in the first few days all the antibody is used up in the neutralisation of the still multiplying antigen. Only when there is an excess of antibody will one observe a rise in serum titre. The argument holds also the other way round: one cannot be sure that the multiplication of virus has ceased after the ninth day just because none is detectable by the routine techniques. Some still might be produced but masked by antibody. Indeed, McKee and Hale (1948) have shown by appropriate methods that this is so.

RECOGNITION OF INFECTION

The rich array of distinct and well-measurable changes, all of them potential diagnostic symptoms, makes the recognition of influenza in normal mice an easy task.

The classical method of assessing lung lesions seems to be inferior to practically all the procedures listed in table I; it is also less convenient because incompatible with the survival of the animal. Among those performed on respiratory washings the direct test for virus by the hæmagglutination technique and the somewhat more sensitive indirect test for viral enzyme activity by inhibitor titration are the most suitable for *early diagnosis*. Both can be performed in an hour and are far less costly than the delicate test for infectivity in eggs. Among those giving *retrospective diagnosis* the titration of serum antibodies is not surpassed in simplicity and specificity by any method—as methods of diagnosis, I hasten to emphasise, not of prognosis.

Less heartening is the second half of the table. In immune mice the presence of virus is masked already in the earliest stages by antibody, and antihæmagglutinin tests are more often than not inconclusive, since initial titres are high. The complement-fixation test, however, comes to our aid. As immunisation with killed vaccines does not elicit the production of complement-fixing antibody, we regard the presence of this antibody as the most reliable sign of past infection. Taken as such, it is about 10,000 times more sensitive than the test for lung lesions. From this discrepancy we have to conclude that the main difference between infection of normal and immune animals is not in the number of infected cells but in the extent to which the virus can multiply.

The irony of the situation is that our most sensitive indicator is also the least known. Eloquent in this respect is the fact that there are no less than three hypotheses, all equally acceptable and unconvincing, to explain the origin of the complement-fixing antigen. It might be materially related to the virus, either as a precursor or as a breakdown product, or it might simply be an abnormal metabolite of the parasitised cell.

TABLE II—CORRELATION OF ANTIBODY LEVELS WITH SPECIFIC RESISTANCE

(Abridged from Fazekas de St. Groth and Donnelley 1950c)

Vaccine	Route	Antibody in		Protection
		Serum	Bronchi	
Live	Nasal *	924	46·0	> 1,000,000
	Peritoneal	1120	2·8	1550
	Subcutaneous	232	1·0	186
Killed	Nasal	156	4·6	3160
	Peritoneal	564	2·2	380
	Subcutaneous	108	0·8	89
Nil	—	<5	<0·5	1

The Melbourne (A) strain was used both for vaccination and challenging.

* Experimental infection with one 50% infective dose of virus.

ANTIBODIES AND RESISTANCE

The fact of antibody combining with its antigen in vitro has led, not infrequently, to the use of serum titres as a measure of immunity—an unfounded assumption, especially in the case of pathogens which do not enter the blood-stream to establish infection.

To find out exactly what is the part of the serological response in resistance we used different types of vaccination, and determined the amount of antibody present in the serum *and* in bronchial washings. The ratio of the two titres is a measure of the *distribution of antibody* between the circulation and the site of possible infection. The answer was rather surprising.

Irrespective of the type of vaccine (live, formol-inactivated, or heat-inactivated), after extrarespiratory immunisation only $^{1}/_{250}$ of the antibody produced is present in the respiratory tract. After nasal vaccination, on the other hand, there is a highly significant shift in favour of the bronchi, the distribution ratio being 1 : 20.

These differences are also reflected in various degrees of resistance. Animals whose serological status was fully known, as regards both the amount and the distribution of antibody, were challenged with live influenza virus. The "protection values" show how many times bigger an infective dose had to be to cause standard symptoms than in untreated normal control animals (see table II).

These experiments, done on large numbers of mice and repeated with different strains of virus, allow of definite conclusions. No method of vaccination conveys any protection against infection with the heterologous type of virus; and it can be stated categorically that the degree of resistance to homologous challenge is not a

TABLE III—PATHOTOPIC POTENTIATION OF IMMUNITY
(Abridged from Fazekas de St. Groth and Donnelley 1950d)

Vaccination	Antibody in		Protection
	Serum	Bronchi	
A-type virus peritoneally ..	564	2·2	380
A-type virus peritoneally and B-type virus nasally	496	7·8	22,400
B-type virus nasally	<5	<0·5	2
Nil	<5	<0·5	1

A-type virus = Melbourne strain, inactivated by formaldehyde.
B-type virus = Lee strain, inactivated by formaldehyde.
All mice were challenged with dilutions of live Melbourne (A) virus.

direct function of the amount of antibody present in the serum, but shows a high positive correlation with the concentration of antibody free in the respiratory tract. In other words, only that fraction of antibody is *immunologically active*—i.e., capable of preventing infection—which meets and neutralises the virus before it can enter a susceptible cell. Specific resistance can be explained by the interaction of virus and antibody in the respiratory tract; *in the case of immunisation with inactive vaccines it seems unnecessary to postulate any further mechanism, whether extracellular or intracellular.*

ENHANCEMENT OF IMMUNITY

A higher degree of protection was achieved by nasal vaccination than by other methods, not because more antibody was produced (in fact, it was considerably less) *but because more of it was present in the immediate* environment of the susceptible cells. The next task was, obviously, to find out *how* this advantageous distribution originated. *It could have been brought* about either by local production of antibody or by *local accumulation of antibody produced* elsewhere. Instinctively we favoured the first view: however, the experiments showed that we were wrong.

Mice were immunised simultaneously with the two types of influenza virus: one of the antigens was given by the nasal route, the other peritoneally. If local production were the answer, bronchial washings should contain a large amount of antibody against the antigen administered nasally, and practically none against the one given peritoneally. The results were *not quite* as expected (table III).

It is clear that nasal administration of an unrelated vaccine, in itself incapable of affording even the slightest protection, increased the efficiency of peritoneal immunisation by 20–100 times. This increase in specific resistance can be attributed to the increase in specific antibody content of the respiratory tract. That is, a vaccine—besides acting as a specific antigenic stimulus—can also initiate a process which leads to the accumulation of unrelated circulating antibodies at the site of immunisation. The dramatic increase in specific resistance was brought about by a *shift in the distribution of specific antibody*—i.e., not by the reinforcement of antibody production but by the strategic use of antibody already present.

This experiment established a method which combines the advantages of the two types of vaccination. Large amounts of antibody are produced—as after peritoneal administration, but without the unfavourable distribution—and high concentrations are reached where antibody is needed—as after nasal vaccination, but without requiring impractically big doses of antigen. The phenomenon was termed *pathotopic potentiation of immunity*, since it involved the administration of an "adjuvant" at the site of future infection. Obviously, it has no relation whatsoever to the enhancement antibody response by the local application of adjuv admixed to a vaccine (Ramon's principle, commo known as Freund's).

In further experiments we furnished what we b is conclusive evidence that *pathotopic potentiation* effective after all commonly used types of influenz vaccines given by any extrarespiratory route. What i *more, it can enhance passive immunity resulting from* the intravenous injection of specific antiserum (Fazek de St. Groth and Graham 1950).

The essential mechanism seems to be a local increa in tissue or capillary permeability induced by the very mild inflammatory reaction to vaccination. Widely different substances—e.g., influenza-virus preparations, live vaccinia virus, the metaperiodate-ion, and compounds with anti-vitamin-K action—which had this one trait in common proved equally effective as *pathotopic adjuvants*, whereas others lacking this property were inactive (Fazekas de St. Groth and Donnelley 1950e).

As inflammation disappears the elevated permeability declines, and with it the potentiating effect. Antibody distribution and specific resistance returned to the level found in the control mice by the end of a month (Fazekas de St. Groth 1950b).

CONCLUSIONS

What does all this mean to the epidemiologist and the physician concerned with *human disease?* Strictly speaking, nothing. Results of animal experiments have little immediate effect on medical routine. They are meant rather to provide food for thinking, and to shape the mental attitude towards problems yet *unsolved. And there is a fair number of these in* epidem influenza.

As regards diagnosis, the disappearance of inhibitor *from the respiratory secretions* of infected animals promises a simple and sensitive presumptive test. Among those applicable in convalescence and suitable to large-scale work on vaccinated groups the titration of complement-fixing antibodies is given high preference. This view, persistently advocated by Hoyle and Fairbrother (1947), is not only supported by work on mice. Study of an epidemic in a population with no *basic immunity* (Isaacs et al. 1950) also showed clearly *the superiority of the complement-fixation test over the* hæmagglutination technique.

The *generally used serological* tests do not measure resistance, which seems to be determined by the amount of antibody in the respiratory tract. The use of serum titres as a synonym for immunity is misleading, and can well explain why there are numerous contradictions and confusing results. Convenience is not an excuse for inaccuracy; and, if an indirect test is to be sub*stituted for a direct one*, we *must insist* first on the demonstration of a strict correlation between the two phenomena.

We have reliable tests for antigens and antibodies, but we cannot predict what the next epidemic strain is going to be like. The complete failure of the latest American wholesale vaccination campaign is a strong warning against complacency. Yet, whatever our future vaccines be, we should aim at making the most of what we have. *Pathotopic potentiation* of immunity might be useful in this respect, since with this method it is possible to "store" antibody in the circulation, and, in case of emergency, to "turn it on" in the respiratory tract.

In the absence of drugs with antiviral effect, combating an epidemic rests on the production of better vaccines. Knowing, however, that *nasal secretions* of even subclinical cases contain enormous amounts of virus, perhaps the handkerchief is not such an obsolete weapon it might have seemed among the more modern uipment of preventive medicine.

CIRCULATORY CHANGES IN THE FOOT AFTER LUMBAR SYMPATHECTOMY

R. B. LYNN
M.D. Queen's Univ., Ont., F.R.C.S., F.R.C.S.E.
ASSISTANT LECTURER IN SURGERY, POSTGRADUATE MEDICAL SCHOOL OF LONDON

H. BARCROFT
M.A., M.D. Camb.
PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF LONDON AT ST. THOMAS'S HOSPITAL

Lewis and Landis (1929) were the first to draw attention to the fact that vascular tone returned to human blood-vessels after sympathetic denervation. They studied the circulation in the hand after cervico-dorsal sympathectomy and noted that on the day after operation the hand was hot and the digital arteries were pulsating vigorously. On the second day the arteries pulsated strongly but the skin had become pale, and by the fourth day the pulsations had subsided.

The return of tone following sympathectomy in man has already been proved by objective methods in the fingers (Freeman et al. 1934, Doupe 1943, Grayson 1948), in the hands (Barcroft and Walker 1949), in the forearms (Grant and Pearson 1938, Wilkins and Eichna 1941, Grayson 1948), and in the feet (Hoobler et al. 1949).

We describe here what we believe to be the first attempt to record the blood-flow changes daily for six days and from one to three months after sympathectomy in a large number of feet.

EXPERIMENTAL

The investigations were made in the department of vascular surgery at the Postgraduate Medical School. The temperature of the ward where the tests were done was fairly constant at 19–20°C. The final test was done under similar conditions in a quiet room in a clinical laboratory.

In most cases the foot was kept under the bed-clothes till the beginning of the test. The patient usually lay flat without pillows to avoid venous congestion of the leg. Flexible wire thermo-junctions (Grant 1935a) were strapped with sticking-plaster to the skin proximal to the base of the nails of the first and third toes of each foot, and the skin-temperature was recorded. The thermo-junction wires were then gently withdrawn from under the sticking-plaster on the toes so that the plethysmographs could be put on for determining the blood-flow. Each plethysmograph was fitted as follows:

A rubber diaphragm with a cuff was selected to fit the leg just above the ankle neatly but not tightly. To prevent leakage of air under the cuff it was lightly bound to the ankles with a couple of turns of non-vulcanised rubber, avoiding venous congestion. A board was put across the foot of the bed and the plethysmograph placed on it. The foot was inserted into the plethysomgraph so that the heel rested on a felt pad. The diaphragm was clamped to the plethysmograph. A collecting cuff was put on about $^{1}/_{2}$ in. proximal to the diaphragm. The tubing from the plethysmograph was connected to the recording apparatus, and the tubing from the collecting cuff to a reservoir of compressed air. The plethysmographs were filled with air (Barcroft and Walker 1949).

After both feet had been fitted up in this way about 10–12 flows were recorded in each foot at intervals of about a minute. Both plethysmographs were then calibrated and removed. The thermo-junctions were

* Foot blood-flow not measured; the figure is that for the other preoperative test.
† The figures are the averages of the foot blood-flows recorded on the fifth and seventh days.
‡ Nine months after sympathectomy.

The thermo-electric skin-temperature meter used for the toe-temperatures on and before the nineteenth postoperative day in case 5 differed from that used on all the other occasions; so the readings may have been too high. For this reason these readings, though shown in fig. 3, are omitted from the table and from the averages.

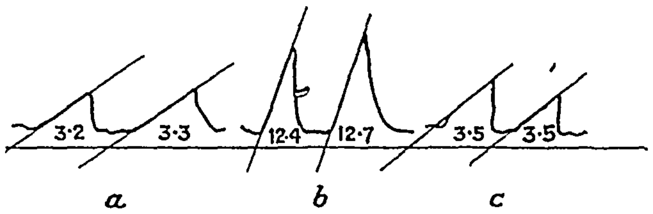

Fig. 1—Plethysmographic tracings of the blood-flow in the foot: *a*, two days before sympathectomy; *b*, first postoperative day; *c*, fourth postoperative day.

gently inserted under the plaster on the toes once again, and a second set of skin-temperatures was recorded.

The patient's temperature and the temperature of the ward were noted. The rate of the blood-flow in each foot was calculated and averaged. The toe-temperatures were similarly averaged.

Before operation foot blood-flows and toe-temperatures were measured twice, on different days. On one of these days, after the resting flows had been obtained, one of the patient's arms was immersed in water at 45°C and he was covered with blankets. The blood-flow in the foot was then measured over three-quarters of an hour during reflex vasodilatation.

In a few patients the foot blood-flows were recorded within a few hours of operation, no assistance being necessary for carrying out the test. In most cases the flow was measured daily from the first to the sixth day after operation and often a few more times in the first fortnight. All except one of the patients returned from one to three months after operation, and the final blood-flows and toe-temperatures were measured after the patients had rested for half an hour.

CLINICAL MATERIAL

The investigations were done on 21 limbs before and after sympathectomy. The accompanying table shows that these have been divided into two main groups: (1) 6 limbs with healthy arteries (hyperhidrosis 4, deep venous thrombosis 2); and (2) 13 limbs with various degrees of arterial abnormality (acrocyanosis 2, c and varicose veins 2, popliteal aneurism 1, and ulceration 2, diffuse obliterative arteritis or art sclerosis 6).

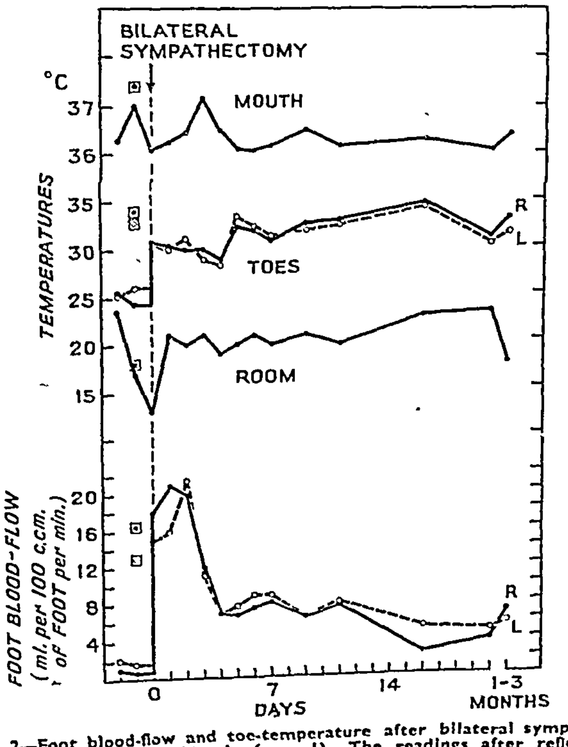

Fig. 2—Foot blood-flow and toe-temperature after bilateral sympathectomy for hyperhidrosis (case 1). The readings after reflex vasodilatation are shown in squares.

The blood-flow in the feet of one patient with ulcers and varicose veins behaved atypically and case is described in an accompanying paper (Lynn and Martin 1950).

RESULTS

Fig. 1 shows a typical tracing of the foot blood-flow. Figs. 2–4 show the results obtained in cases 1, 5, and Fig. 2 illustrates the effect of sympathectomy on the foot blood-flow and toe-temperature in a case of hyperhidrosis in which the arteries were normal. Before operation the blood-flow in the feet was about 1 or 2 ml. per 100 c.cm. of foot per minute. Reflex heating (results enclosed in small squares) increased the blood-flow in the right and left feet to 16·5 and 13·2 ml. respectively. As would be expected, the blood-flow records made a few hours after the sympathectomy showed considerable hyperæmia in both feet (right 18 ml., left 15 ml.). However, the flow continued to increase, reaching a maximum on the first day in the right foot (21 ml.) and in the second in the left (21·4 ml.). After this the blood-flow decreased abruptly to 7 ml. in both feet on the fifth day. No further remarkable changes took place, but it should be noted that the blood-flow remained about four times the preoperative level up to the time of the final test from one to three months after operation.

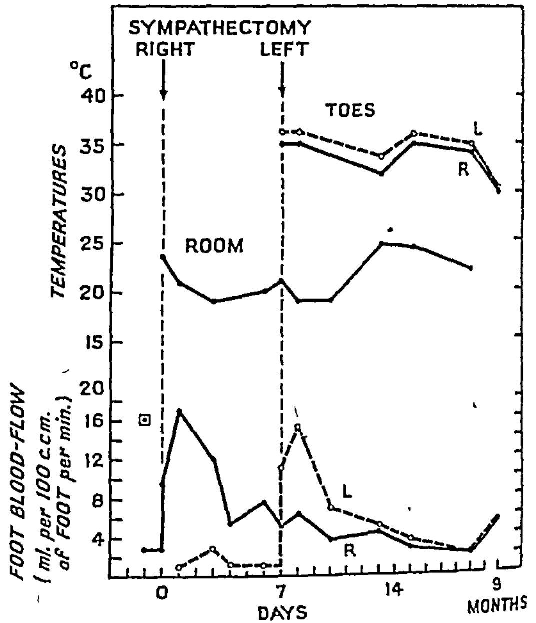

Fig. 3—Foot blood-flow and toe-temperature after bilateral sympathectomy for acrocyanosis (case 5). The reading after reflex vasodilatation is shown in a square.

Fig. 2 also shows the effect of the sympathectomy on the toe-temperature. Before operation the skin-temperature was about equal in both feet at 25–26°C. After operation it rose abruptly and remained up, and from one to three months after operation it was 33°C on the right side and 31·2°C on the left.

When the effects of the sympathectomy on the foot blood-flow are compared with those on the toe-temperature, the striking fact is that the foot blood-flow soon declined from its initial rapid postoperative rate, yet the final toe-temperatures were higher than those during the first few days after operation. The table shows that similar vascular changes took place after sympathectomy in the other feet with normal arteries.

Figs. 3 and 4 are the charts from two cases with arterial disease. Case 5 (fig. 3) had mild acrocyanosis.

mpathectomy was done in two stages, with an interval seven days. Apart from this the blood-flow and the mperature changes, generally speaking, were similar those recorded in fig. 2 in the patient with *normal* teries. As might be expected, the maximum foot ood-flows in the feet with slightly diseased arteries g. 3) were *not* quite so large as those in the patient erated on for hyperhidrosis (fig. 2). Note that nine onths after operation the blood-flow was more than uble the preoperative rate and the toes were very arm.

Fig. 4 shows the effects of sympathectomy on the rculation in the feet of a patient with severe obstructive teriosclerosis. The postoperative increase in foot lood-flow is small, although from one to three months ter it was still about double its preoperative level. The stained elevation of the temperature of the toes is ery striking. Similar changes were observed in the lood-flow in the other feet with abnormal arteries (see able). The table also shows that the average temerature of the toes was above 30°C in 7 of the 11 feet ith diseased arteries tested from one to three months fter operation.

The foot blood-flow and the temperature changes btained before and after sympathectomy in limbs with ormal arteries have been averaged and are shown in fig. 5. Here we see also the average of all the results recorded in the limbs with diseased arteries. The points shown in the average curves are (1) the immediate postoperative increase in foot blood-flow; (2) the maximum on the first or second day; (3) the rapid decline after the first few days: and (4) from one to three months later foot blood-flows about double the preoperative level. In limbs with both normal and abnormal arteries, on the other hand, as fig. 5 shows, the average temperature of the toes was much increased by sympathectomy and remained elevated throughout the investigation.

DISCUSSION

Changes in Blood-flow in Foot

The results just described confirm the clinical observations of Lewis and Landis (1929), who noticed considerable hyperæmia after sympathectomy, followed by a rapid return of tone. In particular they stated that the vigorous pulsations in the digital arteries had subsided on the fourth day—an observation which agrees very well with rapid decrease in the foot blood-flow as measured with the plethysmograph (fig. 5).

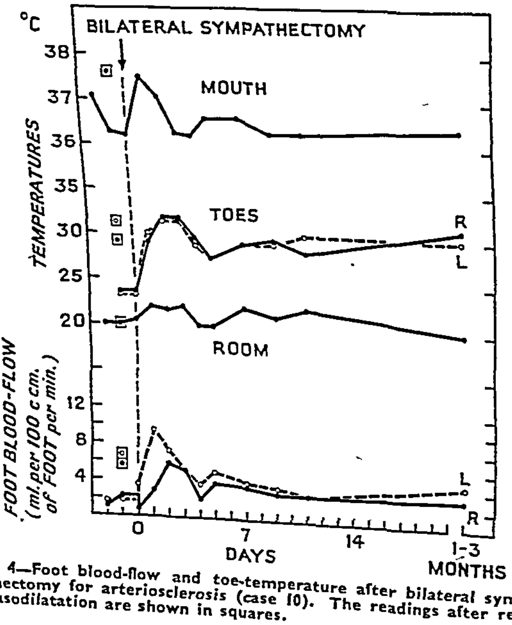

Fig. 4—Foot blood-flow and toe-temperature after bilateral sympathectomy for arteriosclerosis (case 10). The readings after reflex vasodilatation are shown in squares.

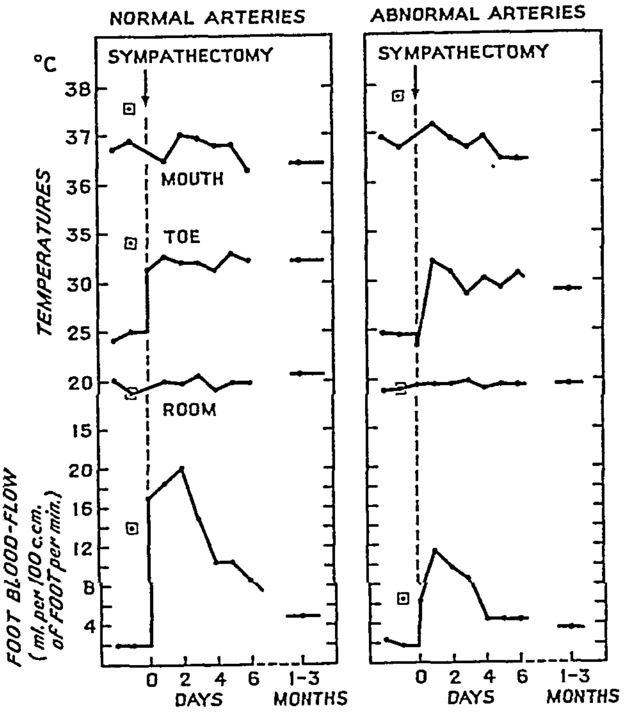

Fig. 5—Averaged foot blood-flows and toe-temperatures in 6 limbs with normal arteries and 13 limbs with abnormal arteries. The readings after reflex vasodilatation are shown in squares.

The most obvious explanation of the increase in the rate of the blood-flow in the feet after sympathetic denervation is a vasodilatation due to release of the vessels from central vasoconstrictor tone. Another possible explanation considered was the action of metabolites released by the trauma of the operation. This, however, was discounted by the fact that, when the limbs were sympathectomised one at a time, the hyperæmia developed only in the sympathectomised foot (fig. 3). Several similar observations were made by Barcroft and Walker (1949) on the blood-flow in the hands after unilateral sympathectomy.

It is curious that the blood-flow in the feet does not usually reach its maximum till the first or second day after section of the sympathetic fibres. This delayed hyperæmic peak was also seen after sympathectomy in some hands (Barcroft and Walker 1949). At present this cannot be explained. It will be seen that preoperative reflex vasodilatation also does not cause maximal hyperæmia.

Another interesting point is that the average maximum foot blood-flow in sympathectomised feet was only about half the maximum blood-flow that Barcroft and Walker (1949) found in sympathectomised hands (feet with normal vessels, maximum average 22·4 ml.; hands, maximum average 46 ml.). This may be because the foot contains a much greater bulk of relatively avascular tissue in proportion to the skin than does the hand.

Rapid Partial Recovery of Tone

The recovery of tone in the vessels of the foot was very rapid between the third and sixth day (figs. 2–5 and table). In this respect the arteries of the foot and hand behave very much alike—blood-flow in the sympathectomised hand had declined to a quarter of its maximum postoperative value by the end of the first week (Barcroft and Walker 1949). The reason for this recovery of tone is not understood. It would be beyond the scope of this article to discuss in detail the theories advanced by various workers to explain it. Cannon (1937) believes *that it is due to an intrinsic property of the smooth* muscle of the arterial wall. One can say with certainty, however, that it is not due to the re-establishment of central nervous tone through some slightly damaged pathway. This follows from the fact that tone returned in the usual characteristic way to the vessels in 4 feet and 11 hands proved by postoperative reflex vasodilatation tests to have been completely sympathectomised. Moreover the phenomenon is very well known in animal experiments in which there can be no question of the completeness of the sympathectomy—e.g., Grant (1935b) found that the arteries of the rabbit's ear recovered their tone about twenty-four hours after all the sympathetica fibres had been cut.

Temperature of Toes

It will be remembered that the temperature of the toes remained high throughout the postoperative period. Lynn and Burt (1949) observed high toe-temperatures as long as four years after sympathectomy. The permanent elevation of the temperature of the toes, yet very considerable subsidence in the blood-flow in the foot, so striking a feature of this investigation, has already been briefly reported by Hoobler et al. (1949). Further work is necessary on the circulatory changes in the toes following sympathectomy. As regards its action on the circulation, the beneficial effects of sympathectomy may be considered from two angles. (1) In acute emergencies, it will tend to produce a large vasodilatation lasting for a few days. (2) In chronic cases, the benefits will probably mainly be due to isolation and protection of the sympathectomised vessels from strong central stimulation excited by cold, &c.; under such circumstances the circulation in a normally ennervated foot may become very small indeed and that through a sympathectomised one is likely to be many times greater.

SUMMARY

The blood-flow in the feet and the temperature of the toes of 19 limbs were determined twice before, daily for the first six days after, and from one to three months after, lumbar sympathectomy.

The average blood-flow in 6 feet with normal arteries (2·1 ml. per 100 c.cm. per minute before operation) was much increased after sympathectomy, reaching a maximum on the second day (20·0 ml.). By the sixth day vascular tone had partially recovered (8·5 ml.), and still more so from one to three months after operation (4·9 ml.). But, the toes in these cases remained permanently warm after operation (preoperative average 24·2°C; from one to three months 32·2°C.).

The blood-flow in 13 feet with abnormal arteries also increased postoperatively and returned to about double the normal. The toes also remained warm.

We are most grateful to Mr. Peter Martin, F.R.C.S.E., for his interest and encouragement, and for permission to carry out these investigations on his patients. The expenses were partly defrayed by a grant from the Medical Research Council to one of us (H. B.).

LACK OF RETURN OF VASCULAR TON IN THE FEET AFTER SYMPATHECTOM

R. B. Lynn
M.D. Queen's Univ., Ont., F.R.C.S., F.R.C.S.E.
ASSISTANT LECTURER IN SURGERY

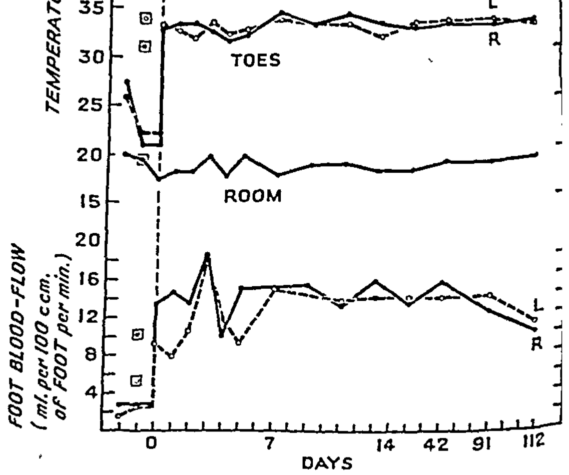
Peter Martin
V.R.D., M.Chir. Camb., F.R.C.S.E.
ASSISTANT SURGEON AND LECTURER IN SURGERY
POSTGRADUATE MEDICAL SCHOOL OF LONDON

LUMBAR sympathectomy is usually performed abolish, or at least diminish, vasomotor tone in the lo extremities and so to increase the blood-flow thro the part. However, Lynn and Barcroft (1950) h shown that after a transient hyperæmia the foot blo flow returns in four to seven days to just above its operative level. The following case is thought to be interest because vascular tone had not returned at end of four months and because the patient complai of the excessive warmth of his feet, particularly at nig

CASE-RECORD

A chef, aged 32, was admitted with seven years' hist of recurrent ulceration of both lower legs following "de sores" which developed in the Middle East in 1942. ulcers healed and recurred at intervals despite excision skin grafting on one occasion. Incompetent varicose ve had been excised without benefit. The patient also co plained of excessive sweating and vasospastic attacks in feet.

On examination bilateral testicular atrophy was fou which the patient stated had been present as long as he co remember. The penis was of normal length, and the pati admitted potence. The distribution of hair and fat slightly feminine. There were ulcers over both me malleoli, with extensive surrounding varicose staining slight eczema. The ulcer on the left ankle was in the mid of a skin graft. The feet were excessively moist and the t cool and slightly cyanosed. All the peripheral pulses w present and full in both limbs. The long saphenous syste in both legs were incompetent. The blood picture was norm and urine analysis negative. 18·7 mg. of 17-ketosteroi



Temperatures and foot blood-flow. The readings after ref vasodilatation are shown in squares.

s excreted in the urine in twenty-four hours (0·87 mg. per 0 ml.). Tests for pituitary hormones showed an excessively h secretion of follicle-stimulating hormone (24, 48, 72 + 96 ouse units in the 24-hour specimen of urine). Radiography the long bones showed no evidence of delayed epiphyseal ion.

Operation.—After bilateral lumbar sympathectomy, multiple ation of the varicose veins, and biopsy of the right testicle, e patient was discharged ambulant, with the ulcers almost aled.

Biopsy Specimen.—The portion of the right testis showed rtually nothing but interstitial cells, only an occasional ubule being found, devoid of spermatic elements. There as no evidence of disorderly growth.

Follow-up.—A month after discharge the patient complained hat his feet were so hot that the rest of his body felt cold. t night his feet burned and tingled so much that he kept hem outside the bed-clothes for relief, and even then the discomfort disturbed his sleep. Examination of his feet howed the superficial veins to be turgescent and the skin f the toes and feet to be abnormally hot to the touch as well s flushing excessively when the patient stood up. About our months after the sympathectomies this "erythermalgic-ike" discomfort had diminished somewhat but was still sufficient to be of real discomfort to him. He reported that the feet were more comfortable if supported by elastic bandages, which he wore almost constantly during the day.

Plethysmographic studies and skin-temperature readings are shown in the accompanying figure. Before operation the foot blood-flows were about 2·5 ml. per 100 c.cm. of foot per minute, and after sympathectomy there was an immediate increase to a maximum of about 18 ml. on the third day, and then, instead of a return to a little above the preoperative level, a sustained hyperæmia, although declining slightly, up to the end of almost four months. Even the skin-temperature readings were somewhat higher than the average after lumbar sympathectomy.

DISCUSSION

The explanation of this anomalous behaviour after lumbar sympathectomy is as unknown as the mechanism of spontaneous return of vascular tone which is the rule (Lynn and Barcroft 1950). Rogers (1935) described a case similar to this in which the patient remarked about his feet that "they feel as if I am walking on hot plates." Rogers offers no explanation for this unpleasant side-effect of flushed feet. Leriche (1946) reports three such cases in which the feet became pathologically hot after lumbar sympathectomy. He states that the feet were burning hot to the touch as well as subjectively, that they were more bearable when the patient lay down, and were relieved by a cold bath. He believes that the condition is due to total abolition of vasoconstrictor tone in the vessels and likens the clinical state to "la causalgie de Weir Mitchell." Simmons (1950) has observed the condition clinically and finds that it tends to diminish in severity after six months.

No-one who has reported this condition has verified the hyperæmia by blood-flow measurements in the affected feet; hence one cannot be certain that their cases are strictly comparable, particularly in view of the fact that many patients complain of undue warmth of the foot after unilateral lumbar sympathectomy. Whether the endocrine imbalance in the present case is of significance is a matter for speculation only. Perhaps after several months or a year some degree of tone may be regained, and this may be suggested by the slight fall in foot blood-flows in this patient at the last reading. This may explain also the slight subjective improvement; or perhaps the patient is merely becoming accustomed to his persisting hyperæmia. However, it remains an unpleasant, unexplained, and unpredictable complication of lumbar sympathectomy for which there is no specific treatment.

SUMMARY

A patient with bilateral testicular atrophy and chronic ulcers of the legs developed an "erythermalgic-like" state after lumbar sympathectomy, owing to failure of return of vasomotor tone to the feet, as measured by the venous-occlusion plethysmograph.

SODIUM THIOPENTONE AS THE SOLE ANÆSTHETIC FOR TONSILLECTOMY IN ADULTS

H. F. GRIFFITHS
M.A., M.D. Camb., D.A.
CONSULTANT ANÆSTHETIST, SOUTH-EAST KENT AND CANTERBURY AREAS

EARLY success with the use of sodium thiopentone as the sole anæsthetic for tonsillectomy in adults (Griffiths and James 1945) led me to think that it had several advantages over methods in more common use. Further experience has justified this belief, and a second series of 220 consecutive cases is presented here in the hope that the method will be employed more widely.

The first series (Griffiths and James 1945) consisted of 133 successful cases in Service personnel. We used a 5% solution of sodium thiopentone in a dosage varying from 13 ml. (0·65 g.) to 70 ml. (3·5 g.). The patient was placed in the Rose position and a Davis gag was inserted, after which a flow of 2 litres of oxygen per minute was administered through the anæsthetic tube on the tongue-piece. We commended the method on the grounds of simplicity, ease of administration, and absence of post-operative complications, but warned against its use by those not skilled in the administration of sodium thiopentone.

Whyte (1946), Fox and Shane (1947), Robertson (1947), and Dickie (1948) all use sodium thiopentone as the main anæsthetic for tonsillectomy; but they add other drugs to it, which is unnecessary. Fisher and Woodley (1949) said that they published their results because they considered that much of the criticism of the method is quite unwarranted. Their technique is almost identical with that of Griffiths and James, except that they spray the nose and throat with 10% cocaine or 2% tetracaine hydrochloride before the administration of sodium thiopentone. The number of their successful cases amounts to 738, but they recommend that the method should not be used for children under the age of 15 years.

METHOD OF ADMINISTRATION

Premedication.—'Omnopon' gr. $^1/_3$ and scopolamine gr. $^1/_{150}$ hypodermically one hour before operation were given as a routine for all patients between the ages of 18 and 60. Below 18 and above 60 half this dose was given.

Induction and Maintenance.—A solution of 5% sodium thiopentone is used in a 20 ml. syringe, and induction takes place in the anæsthetic room. As soon as deep and level anæsthesia is reached, the needle is withdrawn and the patient is transferred to the theatre and put into the Rose position. The needle is then re-inserted and anæsthesia is maintained at the required level by further small and repeated doses of the drug. Usually between 4 and 8 ml. (0·2–0·4 g.) of the solution is required to induce anæsthesia, according to the age and build of the patient. It is injected fairly rapidly and often brings on a short period of apnœa. This need cause no alarm, for it soon passes, and is indeed encouraged as being a valuable gauge of the probable total dose required. Generally between 10 and 15 ml. (0·5–0·75 g.) is necessary to get the patient deep enough for transfer to the theatre, and after this small quantities, varying between 2 ml. and 4 ml., are added as necessary to keep the patient so deep that there is no movement of the pharyngeal muscles. The anæsthetist must ask the surgeon periodically to report on the colour of the patient and whether or not there are pharyngeal movements.

As soon as the jaw is sufficiently relaxed, a standard Boyle-Davis gag is inserted, and a tube delivering roughly 2 litres of oxygen per minute is connected to the tongue-piece. It has been found advisable to administer oxygen, so as to correct the slight cyanosis which may occur if respiration becomes unduly depressed.

The surgeon then performs a dissection of the tonsils, taking particular care that his assistant keeps the pharynx scrupulously clear of blood. This is especially necessary because the laryngeal reflexes are never entirely absent, and the inspiration of blood may cause severe spasm.

Postoperative Care.—The operation having been completed, and all bleeding-points secured, an airway is placed in position as the Boyle-Davis gag is removed. The patient is them immediately turned on his side and a pillow is placed under his occiput in order that any blood or secretions may run out and so be kept from the larynx. In this position he is returned to the ward and left unmoved until consciousness has returned sufficiently for him to eject the airway.

The pharynx and larynx are not sprayed with any local anæsthetic, for it is thought this would increase the liability to inhale foreign substances.

THE PRESENT SERIES

Age and Dosage.—In the 220 cases now recorded, the average age was 28·8 years; the oldest patient was 68 and the youngest 14. There was no selection. The average dose of sodium thiopentone was 28·3 ml. (1·41 g.). The minimum was 13 ml. (0·65 g.) for a girl of 17. The maximum of 50 ml. (2·5 g.) was required in 3 males, aged 16, 35, and 38.

Recovery.—Most patients recovered consciousness within 20–30 minutes of returning to bed, after which they usually fell into a sleep lasting up to 3, or even 4, hours. Postoperative sedative was rarely required, but when needed was given as morphine gr. $^1/_4$ or $^1/_6$ hypodermically. Restlessness was seldom seen, and was easily controlled with morphine. Vomiting was very uncommon, and the general condition of patients was much better than after the anæsthetics more usually employed.

ADVANTAGES

From the surgeon's point of view there are several advantages. He has a motionless pharynx in which to work, and he has more room than when an endotracheal tube is used. He does not have to inhale noxious vapours, and there is less bleeding than with the more usual anæsthetics. It enables him to work more expeditiously, for the time of induction is so much reduced that three adult dissections can be done in one hour.

The method is not suitable for children, and, though simple and safe, it should be employed only by those with considerable experience of sodium thiopentone.

My sincere thanks are due to Mr. C. B. Andreae, F.R.C.S., for his long forbearance and his help in the production of this paper.

A CORD-BLOOD SURVEY OF DI IMMUNITY

COMPARISON OF TWO POPULATIONS

MOLLIE BARR
M.Sc. Lond., A.R.I.C.
From the Wellcome Research Laboratories, Beckenham

IT is now generally recognised that the most importa factor to be considered in the immunisation of ver young babies against diphtheria is the amount of anti toxin derived from the maternal circulation and st present at the time of the first injection of prophylacti too much antitoxin may neutralise and so render ine the injected antigen.

My colleagues and I (Barr, Glenny, and Randall 194 found that babies lose their maternally conferred ant toxin at a steady logarithmic rate, and that the approx mate titre remaining at any given age can be calculate from the cord-blood value. We have shown (195 that babies can be successfully immunised by tw injections, each of 0·5 ml. of A.P.T., provided that the passive antitoxic titre has fallen below 0·04 unit per m at the time of the first injection of prophylactic. W also calculated that over 80% of a population of 2 babies born in south-east London would be effectivel immunised if they received their first dose of A.P. at the age of 3 months, the maternally conferred antitox in these babies having fallen below 0·04 unit per ml. a that age. We suggested that antitoxin estimations on limited sample of cord-blood specimens obtained fro different districts would provide a good general pictu of the immunity state of the newborn, so that methods o immunisation could be devised which would be the m satisfactory for the majority of babies.

ANTITOXIC TITRES OF CORD-BLOOD SAMPLES

Between July, 1949, and January, 1950, random specimens of cord-blood from different districts have been investigated at these laboratories, 100 samples being used from each district, to determine whether the conclusions of Barr et al. (1950) are of general application. In the course of this work it has been found that the percentage of samples with no detectable antitoxin obtained from any one district may not give any indication of the antitoxic values of the remainder, and that the Schick test, whether done on mothers after delivery or on the babies at a given age, such as 3 months, would not provide useful information about when to start immunisation of the babies. These points can be well illustrated by considering the results obtained from some districts, of which Coventry has been chosen here as an example to compare with Southwark, the figures for which have already been published (Barr et al. 1949). Results of antitoxin tests for these two districts are given in table I.

Tests were made by the guineapig intracutaneous method, the lowest value for which tests on human sera can be made with certainty being 0·001 unit per ml. All values in this particular investigation were tested at about 100% differences, because the large scatter rendered closer testing unnecessary; in the determination of means of logs each value was taken as the mean of the logarithmic limits within which it lay.

It will be seen from table I that there were twice as many samples with no detectable antitoxin from Coventry as there were from Southwark, and statistical comparison of the numbers with and without detectable antitoxin from these two districts shows that the differences are highly significant ($\chi^2 = 10{\cdot}219$, $n = 1$, $P = 0{\cdot}002$). A comparison of the general scatter of values shows that, although there are more samples between 0·001 and 0·01 unit per ml. in the Coventry series, the main peak of both distributions occurs at 0·2–0·5 unit, the peaking in value being more pronounced in the Southwark es. The highest value recorded was 5–10 units oventry, and six samples from Southwark and seven Coventry contained over 1 unit per ml. A comparison he means of the logs of values over 0·001 unit per gives a value of $t \doteq 1{\cdot}586$, $n = 135$, and $P = 0{\cdot}116$. is, though the difference between the numbers of ples with and without detectable antitoxin is highly ificant, the numbers containing over 1 unit per ml. almost identical and the difference between the ans of the logs of values of those with detectable itoxin is not significant. In these particular distributions, therefore, the proportion of samples with no ectable antitoxin gives no indication of the mean lue or of the scatter of the remaining samples.

Any investigation of the immunity state of very young bies should be made by antitoxin titrations on blood mples. Making titrations at 10% differences (Barr al. 1949) showed that the antitoxic titre of cord-ood was usually appreciably higher than that of the other's blood taken during labour, the ratio varying om 1·00–2·23, with an average figure of 1·57. We und that the best straight line representing the logarithmic rate of loss of maternally conferred antitoxin in babies cut the axis at a point 36·9% below the cord-blood value. Owing to individual differences in the ratio of titres, cord-blood : mother's blood, a better way to investigate the immunity state of the newborn would be the titration of blood samples from the babies, but this is impossible on a large scale. On the other hand, the differences between the ratio of titres are of the same order as the error of the antitoxin titrations made at 100% differences. Thus in practice very good agreement is usually obtained between the amount of antitoxin found by titration of a blood sample from a baby at any given time after birth and the amount expected to be still present at this time as calculated from the cord-blood value. It therefore seems that the best and most practical method of investigating the immunity state of young babies is the titration of cord-blood; from the values so obtained the amount of antitoxin still present at later ages can be calculated with fair accuracy by the formula $\log A_w = \log A_c - 0{\cdot}20 - 0{\cdot}065\,w$, where A_w is the antitoxic titre of a baby w weeks old and A_c is the cord-blood value (Barr et al. 1949).

AGE AT WHICH BABIES REACH THE SCHICK-POSITIVE STATE

The results of titrations of cord-blood samples from Southwark and Coventry have now been used to estimate the approximate Schick-positive rates and the numbers of babies whose antitoxin values would have fallen below 0·04 unit per ml. at various ages and so could profitably receive a first dose of 0·5 ml. of A.P.T.

In estimating the numbers of babies expected to be Schick-positive at any given age, the Schick level has been taken as being between 0·002 and 0·004 unit of antitoxin per ml. This level would be generally accepted as suitable in adults, though some with antitoxic values of 0·004 unit or more might give positive Schick reactions, and others with 0·002 unit or less might be Schick-negative. It seems, however, that the reliability of the Schick test in relation to circulating antitoxin has not been investigated in babies, and so failure to react to the Schick dose may be due either to the neutralisation of the dose by passive maternal antitoxin or to the relative insensitivity of very young babies' skin to the toxin. Until Schick reactions and antitoxic levels are compared in babies, it is impossible to draw accurate conclusions as to the meaning of the Schick-negative state in the very young. In most cases where discrepancies have been encountered in the Schick reactions of mothers and their babies when tested within a few days of delivery, the babies have not shown any reaction while their mothers have reacted; this has been most usual when the reactions of the mothers were not very obvious (Wright and Clark 1944). Owing to this uncertainty in the interpretation of Schick reactions in young babies the assumption is being made here that babies whose antitoxic values are below 0·004 unit would be Schick-positive, and those with values above 0·004 unit would be Schick-negative. The term "Schick-positive" therefore refers to babies with less than 0·004 unit of passive antitoxin per ml. The number estimated as Schick-positive at birth has, however, been given as those for whom the *cord-blood* values were below 0·004 unit per ml. In view of the higher titre of cord-blood, it is probable that this figure gives too low an estimate, and that some of the babies with cord-blood values between 0·004 and 0·01 unit per ml. should be included. The numbers of such babies in these particular populations are very small, however, there being only three at Southwark and four at Coventry. Calculations of values for the age of 1 month and later were made from the formula given above.

The results of these calculations, given in table II, show that 23% of the Southwark babies and 48% of the Coventry babies were born with antitoxic values below the Schick level. If the Schick test were delayed until the babies were 3 months old, 38% and 63% respectively would be expected to be Schick-positive. From the point of view of interference of antitoxin with active immunisation, however, the Schick level is of no practical importance. This is evident from the second and third lines of figures in table II, which show that those babies whose titres are below 0·04 unit per ml.

TABLE II—CALCULATED PERCENTAGE SCHICK-POSITIVE RATES AND CALCULATED PERCENTAGE OF BABIES WHO COULD RECEIVE THEIR FIRST DOSE, 0·5 ML. OF A.P.T., AT VARIOUS AGES

Age (months)	Percentage with titres below 0·004 unit/ml. (Schick-positive)	
	Southwark	Coventry
0	23	48
3	38	63
..	Percentage with titres below 0·04 unit/ml. (ready to start immunisation)	
0	37	62
1	54	72
2	64	78
3	82	89
4	91	92
6	99	99
8	100	100

at birth, and who can profitably receive their first injection of prophylactic in the first few weeks of life, become Schick-positive only at the age of 3 months. Calculation shows that about 3 months elapse between the times at which the maternally conferred antitoxin falls from the level at which immunisation can be started (below 0·04 unit/ml.) to the Schick level (below 0·004 unit/ml.). *Thus information based on Schick testing is* always obtained 3 months in arrears if it is to be applied to the age at which immunisation can be started.

Statistical analysis of portions of the table reveals the following facts concerning the two populations:

(1) The differences between the Schick rates at birth are highly significant ($\chi^2 = 13{\cdot}647$, $n = 1$, $P = <0{\cdot}001$).

(2) The differences between the Schick rates at 3 months are highly significant ($\chi^2 = 12{\cdot}501$, $n = 1$, $P = <0{\cdot}001$).

(3) The difference between the numbers of babies who can be satisfactorily immunised at the age of 3 months is not significant ($\chi^2 = 1{\cdot}976$, $n = 1$, $P = 0{\cdot}17$).

These points seem to show that Schick testing of babies *at various ages would provide information* which is only of academic interest, and if unsupported by antitoxin titrations might lead to erroneous conclusions in the comparison of populations.

AGE AT WHICH TO START IMMUNISATION

Other points of interest shown in table II are that all babies from both populations could be satisfactorily immunised starting at the age of 8 months, as is now officially recommended; on the other hand, over 80% would be effectively immunised if they received their first dose when 3 months old, and at the age of 8 months a large proportion of the babies would have lost nearly all their maternally conferred antitoxin and would thus be unprotected. In referring to successful immunisation the criteria we recommended (Barr et al. 1950) have been accepted; we obtained in babies, at least 2 months after the second injection, normally distributed log antitoxic values with a small scatter round a mean value of 0·2 unit. We suggested, however, that all babies, except those born of potentially immune mothers further immunised during pregnancy, could be successfully immunised by three injections of prophylactic given at the age of 3, 6, and 18 months. This suggestion could be applied to the two populations at Southwark and Coventry discussed here.

DISADVANTAGE OF IMMUNISATION OF EXPECTANT MOTHERS

It seems unfortunate that the immunisation of expectant mothers, to confer passive immunity on their offspring, should recently have been advocated by Bradley (1949). The scatter of values of cord-blood antitoxin is far greater after immunisation, and, as we have shown (Barr et al. 1950), may range from under 0·001 to 120 units per ml. Such high values would not be detected by the Schick test, which was used by Bradley in his work. It is clear that immunisation during pregnancy, by widening the scatter of antitoxic values in the babies, would make it very difficult to formulate a scheme for immunising babies which would be suitable for the majority.

SUMMARY

The immunity state of the newborn in various districts in the British Isles is being investigated by carrying out antitoxin titrations on 100 cord-blood samples from each.

The results from two districts are compared here. In one district the number of babies born without detectable antitoxin was double that in the other. In both districts, however, over 80% of the babies would have been effectively immunised if they had received their first injection of 0·5 ml. of A.P.T. at the age of 3 months instead of waiting until 8 months, as is now officially recommended.

These figures were obtained by calculation cord-blood values, and represent the numbers of in whom the titre of maternally conferred would have fallen below 0·04 unit per ml. This level is reached about 3 months before the babies be expected to become Schick-positive.

It has been found that the number of babies in *samples with values below the Schick level of* at birth does not give a reliable indication of antitoxic values present in other babies.

Active immunisation of expectant mothers, to give increased passive immunity to the babies, be deprecated. Maternal immunisation would the antitoxic level in most, but not all, the babies, it would also increase the scatter of these levels, making it impossible to decide when to begin primary course of immunisation in the babies with a reasonable hope of a good response in the ma of them.

I wish to thank Dr. J. F. Galpine, medical superintend of the Isolation Hospital, Coventry, for his interest coöperation in supplying cord-blood samples, and Mr. H Duval, *consultant obstetrician and gynæcologist*, for perm *ting and facilitating their collection from a maternity* u in his charge.

PRIMARY ATYPICAL PNEUMONIA WIT HEPATITIS AND NEPHRITIS

J. C. Ryle
D.M. Oxfd
GENERAL PRACTITIONER, SHREWSBURY

The following case is reported because the association of atypical pneumonia with hepatitis and nephritis appears to be unusual. Reimann (1947) refers to the occasional occurrence of hepatitis in atypical pneumonia, but two other probable examples were seen in this practice in the same month as the case to be described.

A previously healthy schoolmaster, in the early forties, developed a sudden pyrexia one evening after having had a cold for a few days. Next morning he had a temperature of 103·4°F, pulse-rate 88, and slightly increased respiratory excursion though not rate; fine crepitations were audible at the base of the left lung.

Treatment.—The patient was put on full doses of sulphadiazine and, when in the evening his temperature rose to 104·8°F, on procaine penicillin 600,000 units daily. On the second day a patch of bronchial breathing appeared at the left base. On the fourth day severe vomiting and jaundice of an obstructive type appeared. The sulphadiazine was stopped. On the seventh day, the temperature, which had fallen by lysis to 98–100°F, rose suddenly to 103°F, and fine crepitations were heard all over the right lower lobe. The jaundice meanwhile had persistently deepened and anorexia was complete. On the tenth day the patient was still running a remittent fever up to 103°F, and penicillin was stopped. On the eleventh day a heavy cloud of albumin was noted in the urine and a wet film showed a few red cells and a moderate number of cellular and granular casts.

The patient's condition remained static for a week, with a remittent fever up to 101°F, pulse-rate persistently below 8 minimal and varying pulmonary signs, deep jaundice, and continuing presence of albumin, cells, and casts in the urine. At the end of this week Dr. Ernest Bulmer was called in consultation and kindly arranged a supply of 'Aureomycin,' treatment with which was begun on the eighteenth day of the disease. During the previous twenty-four hours there had been slight signs of spontaneous improvement in that the amount of bile pigment and albumin in the urine decreased and the patient felt better; nevertheless within twenty-four hours of the start of aureomycin therapy the patient's *temperature dropped to normal and did not rise again*, and ll other aspects the patient rapidly improved. By the nty-fourth day the urine was free from bile pigment and ımin, but a few casts were noted until the thirtieth day. reafter convalèscence was rapid.

nvestigations.—On the fourth day radiography of the lungs wed a congested appearance of both lung fields. On the enth day a blood-count showed hæmoglobin 108% and te cells 5000 per c.mm. (differential count normal). On twelfth and nineteenth days agglutinations for *Leptospira rohæmorrhagiæ* and *L. canicola* were negative. On the hteenth day agglutinations for typhoid and paratyphoid ups, composite salmonella, *Brucella abortus*, and proteus re negative. On the same day blood and urine were tured and after thirteen days' incubation were sterile. the sixtieth day cold agglutination did not occur. A nplement-fixation test was negative at $^1/_8$ dilution for the ttacosis-lymphogranuloma group of viruses.

ly thanks are due to Dr. Ernest Bulmer for his assistance l-advice.

Medical Societies

CIETY OF MEDICAL OFFICERS OF HEALTH

Poliomyelitis

THE fever hospital medical services group of the ciety of Medical Officers of Health held a two-day mposium on Poliomyelitis in London on May 19 and , under the chairmanship of Dr. E. G. BENN, president the group.

EPIDEMIOLOGICAL ASPECTS

Dr. W. H. BRADLEY pointed out that the disease had ddenly become pre-eminent in the field of communicable seases in this country. The first real epidemic in Great ritain occurred in 1947 when the attack-rate in England ıd Wales was 18 per 100,000 living—four and a half mes as great as the 1938 high figure and comparable ith the rate in the U.S.A. in 1916 and 1946. In 1947 e number of deaths was about three times as great as 1938; but the case-fatality was only 9%, compared ith 16% in 1938. The age-distribution showed the pward trend characteristic of recent epidemics in vilised countries; 55% of the deaths registered were persons over 15 years of age. The geographical stribution showed a departure from the former rural reponderance, and there was evidence of spread into e rural areas from the cities. The epidemic began in number of widely separated places at about the same me, but not necessarily simultaneously. In these aces some warning of the impending autumnal epidemic as given by a higher incidence than usual at the ginning of the year. There was some evidence of ncentric spread from these centres in the early stages, ut this was soon lost in the general spread.

In 1948 there was a "hangover" from 1947, and a milar effect appeared in the present year after the 1949 pidemic, which was second only to that of 1947. The pidemic of 1949 began a little later than that of 1947 ut lasted longer. In 1947 the peak weekly figure of 08 cases was reached in the 36th week of the year; in 949 the peak figure (463) was in the 43rd week. The hole country was involved in both epidemics; it was ot the general rule that areas lightly attacked in 1947 ere heavily attacked in 1949.

Useful information about the epidemiology of poliomyelitis was provided by the Jersey outbreak in 1948. he island escaped in 1947 despite many visitors from reat Britain. The outbreak suggested a harbinger case, he survival of infection in the area, and a subsequent utbreak.

Dr. Bradley said that in this country Dr. A. H. Gale, r. J. K. Martin, and Dr. D. H. Geffen, and in Australia r. B. P. McCloskey, had been instrumental in discovering the association of poliomyelitis with immunising injections. Prof. Bradford Hill had conducted a statistical inquiry for the Ministry of Health, and had found an undoubted association between recent inoculation and paralysis affecting the injected limb; the finding was most evident with A.P.T.-pertussis vaccine, and less so with A.P.T.; the figures for pertussis vaccine alone were inadequate for drawing conclusions. The risk of poliomyelitis after injections had not yet been determined, but some idea could be obtained from a report that among 1453 cases of poliomyelitis in the age-group 0–4 years there were 26 cases of recent inoculations, not all of which could be regarded as responsible. The task of obtaining reliable information was formidable and required controlled investigation.

Dr. Bradley also reported 12 examples in one year of cross-infection with poliomyelitis in hospitals which, with one exception, were general hospitals. Direct spread merited greater attention. Off-season immunisation might be desirable for nurses in fever hospitals, and subcutaneous injections might be safer than intramuscular; but immunisation should not be discouraged.

ASSOCIATION WITH INOCULATION

Dr. B. P. MCCLOSKEY (Melbourne) reported that during the routine investigation of poliomyelitis in Victoria attention was directed to cases following inoculation. It was concluded that during 1949 recent inoculation with pertussis vaccine, either alone or in combination, was associated with the onset of paralytic poliomyelitis; that the mean interval between such an inoculation and the onset of poliomyelitis corresponded with the presumed incubation period of poliomyelitis; and further that during the 1949 epidemic the actual number of cases of paralytic poliomyelitis was increased by the administration of these inoculations. The severity of paralysis in patients with a history of recent inoculation of pertussis vaccine, either alone or in combination, was significantly greater than in those with no such history. The evidence that recent inoculation with diphtheria prophylactic was associated with the onset of paralytic poliomyelitis was much less conclusive, but could not be dismissed as fortuitous.

The difference from the findings in Great Britain, where the evidence against diphtheria immunisation was strong and that against pertussis vaccine weak, might be explained by the fact that in Australia diphtheria prophylactics were given subcutaneously and with little local reaction, whereas pertussis was given intramuscularly and was commonly followed by reaction; in Great Britain A.P.T. was the common prophylactic and was given intramuscularly.

BULBAR POLIOMYELITIS

Dr. W. HOWLETT KELLEHER observed that though "bulbar" poliomyelitis strictly implied only medullary involvement, the term commonly included involvement of the brain-stem. In polioencephalitis, spasticity and other symptoms had been attributed to damage to the brain-stem; but some of these symptoms might be due to cerebral hypoxia. The incidence and severity of bulbar lesions varied between different epidemics. In 1947 the proportion of cases was higher but the severity was less than in 1949—a bad year. The Minnesota Research Commission classified "bulbar" poliomyelitis into: (1) the cranial-nuclei group; (2) the respiratory-centre group; (3) the circulatory-centre group; and (4) the encephalitic group. Combinations occurred, and the first group could be subdivided into upper and lower subgroups. Palsies involving the upper cranial nerves (5th, 7th, and 8th) were common and mild, and in 1947 gave rise to little anxiety. Involvement of the lower cranial nerves, particularly damage to the 10th nucleus, was associated with the dangerous features of bulbar poliomyelitis, and was prominent in the bulbar forms in

1949. Neurogenic dysfunction of the pharyngolaryngeal area, with large pools of secretions and interference with the airway, gave rise to grave anxiety though treatment was now more promising than formerly.

Involvement of the respiratory centre was difficult to recognise clinically although histological evidence of involvement was common. Some of the symptoms had been ascribed to hypoxia. Circulatory-centre involvement was not recognised in any of Dr. Kelleher's cases. Encephalitic symptoms were exceedingly common, but here again hypoxia might be responsible. The whole problem of bulbar poliomyelitis seemed to be bound up with defects of oxygen concentration. By contrast with poliomyelitis, laryngeal diphtheria necessitating tracheotomy did not seem to cause postanoxic cerebral damage. Factors which added to anoxia were pooling of pharyngeal secretion, reflex laryngeal spasm from the aspiration of small quantities of secretion, abductor paralysis of the larynx, pulmonary atelectasis, pneumonia, and pulmonary œdema. The first three might cause rapid asphyxia.

Drugs, antisera, and antibiotics were not effective against poliomyelitis. Curare had been used to relax muscles in spasm; and this seemed a rational procedure. Hot compresses alleviated tightness of respiratory muscles. Attempted correction of the fluid balance was not without dangers of over-hydration. Intravenous glucose had been used for cerebral dehydration. Nasal feeding must be used with the greatest caution, for collapse and death had followed feeds. Oxygen therapy was clearly indicated in selected cases, but the airway must be free. A free airway might be secured by postural drainage, intermittent or continuous pharyngeal aspiration, or intratracheal aspiration. In the supine position as much as 45° tilt might be needed for drainage; in the prone position the angle was less. Tracheotomy should be, not an emergency operation, but carefully planned. To those who favoured it there were many indications for its early performance; indeed some claimed that it was indispensable before treatment in a respirator, to ensure a clear airway. Tracheotomy was sometimes carried out with a bronchoscope or endotracheal tube in place. A high tracheotomy allowed subsequent nursing in a respirator. The Stille and the Moynahan collarless respirators had advantages in this type of case. Positive-pressure oxygen therapy was required if there was suspicion of pulmonary œdema. The respiratory-centre and circulatory-centre groups responded poorly to these measures.

RESPIRATORS

Dr. W. **Ritchie Russell** (Oxford) observed that life in a respirator was highly precarious; yet decisions had to be made on inexact criteria, and so these were often deferred until severe anoxia had developed. The usual criteria were the extent of the chest movements, the patient's colour, and the sound and strength of the cough; and Dr. Kelleher determined how many numbers the patient could say in one breath. All these standards were crude. Correct speeds and pressures in the respirator were difficult to determine; over-ventilation developed insidiously and might be as disastrous as under-ventilation. An easy method of recording tidal air and vital capacity was urgently needed, not only for deciding on the necessity for the respirator, but for determining its efficacy. In the study undertaken by his team a recording spirometer was used. For research purposes the alveolar carbon dioxide must also be studied. When breathing became difficult the patient's anxiety influenced a decision as to whether a respirator should be used. He suggested that at this stage a strong sedative or anæsthetic might be administered. The difficulty was to decide which was safe; any sedative which gave rise to vomiting was dangerous and might cause death. For postural drainage in the respirator the prone position, with frequent changes of posture, was worth furth because a good tidal air could be obtained in this pos Support for the patient and a better neck-seal required. Other improvements in respirator d suggested by Dr. Ritchie Russell were accurate and rate of control of the motor, temperature control, quick method of tilting, an alarm system to indic failure of pressure, and adequate ports for nursing and setting up intravenous transfusion and blood-press recording apparatus. With every respirator it desirable to have a lung inflator or, better, a suck-bl machine which would maintain respiration adequat when the patient was temporarily removed from th respirator. Inquiry was also needed as to the best meth for weaning the patient from the respirator.

Dr. R. B. **Bourdillon** urged investigation int better measurement of the patient's breathing. Carbo dioxide meters were best; special spirometers or, failing them, spirometers from B.M.R. machines were valuabl It was possible to measure breathing roughly by usin an anæsthetist's bag and elephant tubing. He demo strated a simple improvised bellows for providing a roug idea of a fading vital capacity; for tidal air a similar bu smaller bellows could be used. Tidal air should neve exceed 600 ml., and preferably it should not exceed 500 ml Among the dangers of over-ventilation was cerebra anoxæmia from constriction of the cerebral vessels.

TREATMENT IN THE POST-ACUTE STAGE

Dr. C. D. S. **Agassiz** (Carshalton) remarked that case were now accepted for physiotherapy as soon as possibl after the painful phase. He was impressed by the bette condition of those who had received hot packs and by th unsatisfactory "tightness" of those immobilised i splints or plaster casts.

The child was nursed flat in bed with a firm mattre or bed-board and with a foot board. A simple restraine was necessary to prevent the child sitting up. In th prevention of deformities attention must be directed n only to paralysis but to tightness, which interfered wit the functions of the underlying muscles. Failing hot packs, the affected limbs were sprayed alternately with hot and cold water until the skin was flushed; the patient then lay in a bath of warm water for 10-15 minutes; he was dried, and physiotherapy was begun. Passive movement was restricted by "tightness," which was gradually overcome by regular stretching, short of producing pain. The physiotherapist instructed the child in muscle movement; and when his feet could be brought to a right-angle he was made to stand, with support. Re-education in walking then began. Elbow crutches were preferred to arm crutches. With lengthy re-education a patient with complete flaccid paralysis of both lower limbs could walk with sticks. Callipers were a last resort. Instruction to parents and attendance at aftercare clinics were essential.

Mr. R. H. **Metcalfe** (Carshalton) supported Sister Elizabeth Kenny's ideas on pathology and therapy. Poliomyelitis was not the localised disease it was once thought to be. It involved not only nerves but also nerve end-plates, muscles, fascia, and skin, which become tight and needed to be stretched. Splinting was to be condemned and was probably responsible for short limbs. Moist heat and stretching relieved tightness. He emphasised the importance of enthusiasm and optimism among patients and staff.

Mr. A. **Rocyn Jones** held that the orthopædic surgeon must collaborate with the physician from the beginning. As soon as patients were fit their muscles must be trained for an occupation. Occupational therapy had two advantages: it encouraged muscles which were recovering, and it directed the patient's attention away from his disability. In both physiotherapy and occupational therapy fatigue in recovering muscles must be led, and patients must be handled gently. Two s of occupational therapy were particularly suitable oliomyelitis—modelling and weaving. At the end ½–2 years the permanent disability could be assessed a decision made as to whether any operation or iance could help. If possible, callipers should be ded. The basic operation was arthrodesis; tendon splantation was disappointing. In the rehabilitation hildren leaving hospital, ordinary schools, if practic-, were better than schools for physically defectives. phasis should be on the patient's capacity, not his apacity, so as to overcome the feeling of inferiority. training-schools young patients (aged 16–21) should grouped together, not mixed with adults disabled industry.

FURTHER COMMENTS

The **President** was surprised at the evidence of cross-ection. He thought it of interest that inoculation liomyelitis should occur after immunisation against phtheria and whooping-cough, whose toxins affected e nervous system. The grouping of cases of polio-yelitis in big centres would help to overcome the fficulties of nursing and equipment. He also had perience of distress with nasal feeding, and he preferred introduce the tube into the stomach.

Dr. G. **Breen** compared the geographical incidence f poliomyelitis in London in 1947 and 1949. In 1947 he disease started in London and was heaviest in the South-East. In 1949 the incidence was greatest in the prosperous North-West and lightest in the East and South-East, some poor areas remaining free. Thus the distribution was the reverse of 1947; there were examples of more than one overt case per family; in institutions multiple cases were common: and the age-distribution reverted to a younger group, possibly because of inoculation. Complaints that some batches of combined A.P.T. and pertussis prophylactic were causing severe reactions and might determine the onset of inoculation poliomyelitis influenced the replacement of A.P.T. by P.T.A.B., which could be used subcutaneously. Dr. **Kelleher** found no correlation between the degree of reaction and local paralysis in an experience extending over nine years.

Dr. J. F. **Warin** (Oxford) was alarmed at the effect a few cases of local poliomyelitis were having on the whole diphtheria immunisation campaign; a sense of proportion must be preserved. Dr. G. E. **Harries** (Cardiff) expressed the view that modification of the immunisation campaign might be desirable during poliomyelitis epidemics.

Dr. A. **Joe** (Edinburgh) said there was very little poliomyelitis in Scotland in 1949. Notification was unreliable; only about one-third of the cases were of true poliomyelitis; there was too great readiness to accept a diagnosis of non-paralytic poliomyelitis. Other infections of the central nervous system, including canicola fever, were sometimes called poliomyelitis. He mentioned a ward outbreak in which paralyses were localised by injections of penicillin.

Dr. J. F. **Galpine** (Coventry) thought that syringe infection had not yet been excluded as a cause of poliomyelitis after inoculation.

Dr. W. **Gunn** said that tracheotomy was indicated if there was excessive pharyngeal secretion, and intubation if there was not. Curare could be used for rigidity of the chest.

Dr. H. **Stanley Banks** described a case of neurogenic dilatation of the stomach heralded by sudden vomiting and distension. Dr. **Ritchie Russell** said that acute dilatation in the acute stages was not uncommon; the cause was uncertain, but the respirator could contribute by sucking in air. Dr. **Kelleher** had found acute dilatation not only in the acute stage but also later—sometimes much later. Treatment consisted in passing a stomach tube, washing out the stomach, and prohibiting oral feeding. Other causes of death were bronchopneumonia, atelectasis, chronic urinary infections with renal concretions, and failure of the respirator because of either mechanical or nursing deficiencies. Dr. J. S. **Anderson** had also seen a long-standing case die of acute dilatation of the stomach.

Dr. M. **Mitman** (Dartford) emphasised the importance of muscle spasm and cerebral anoxia in the symptomatology of bulbar poliomyelitis, and agreed on the desirability of some method of measuring respiration. Differences between pharyngeal paralysis in diphtheria and in bulbar poliomyelitis might be ascribed to the presence of spasm in the latter. Cerebral damage attributed to infectious agents and their toxins might be the result of cerebral hypoxia: he suggested that the convulsions of whooping-cough were the result of such oxygen deficiency caused by a paroxysm of coughing which emptied the lungs of residual air. He strongly supported the plea for investigation into the use of the prone position in treatment. Kenny's treatment had first been condemned as no improvement over orthodox methods; then accepted as of value while her "osteopathic" pathology was dismissed; and now even this was accepted. Professor A. **Topping** said that Sister Kenny deserved credit for her influence in changing orthopædic opinion.

Reviews of Books

Physiology in Diseases of the Heart and Lungs

M. D. **Altschule**, assistant professor of medicine, Harvard Medical School. Cambridge, Mass.: Harvard University Press. London: Oxford University Press. 1949. Pp. 368. 40*s*.

Because their approach to each subject is different, there is often a hiatus between physiology and clinical medicine. But in this study of the heart and lungs, Dr. Altschule has succeeded in drawing the two together.

His first and longest chapter treats of chronic cardiac decompensation; its features are analysed and the methods of investigation are assessed. The cardiac output, peripheral circulation, lung volume, blood gases, œdema, and renal and hepatic functions are considered in detail, with long bibliographies appended. The view that acute pulmonary œdema is due to failure of the left ventricle is not regarded as acceptable from a physiological standpoint, and the possibility of a neurogenic factor is discussed. In a chapter dealing with cardiac tamponade the early development of ascites (ascites præcox), usually well in advance of œdema of the legs, is attributed to severe liver damage resulting from raised venous pressure; but cases of constrictive pericarditis, in which the venous pressure may be raised for years, do not often show gross hepatic changes. The help given by cardiac catheterisation has added greatly to the value of the studies in congenital heart lesions and in valvular disease; these have been related particularly to the possibilities of surgical treatment. Shorter sections on lung fibrosis, emphysema, and inflammation deal with alterations in lung volume, cardiac function, and blood gases, but according to the author the data do not suffice for anything like a complete analysis.

Throughout the book deliberate suppression of theory has made the argument in parts a little heavy and lacking in force, especially as the reader may feel that Dr. Altschule himself might have a good deal more to add. The fact remains that the novelty of approach and conception makes this work most valuable to the student of heart and lung diseases.

Morbus Cæruleus

An Analysis of 114 Cases of Congenital Heart Disease with Cyanosis. Editor: E. **Mannheimer**. Basle: Karger. 1949. Pp. 332. Sw. fr. 40.

The international character of medicine is well illustrated in this work, which is produced by a group of doctors from Stockholm, dedicated to two Americans, written in English, and published in Switzerland. The study is based on 114 patients suffering from congenital cyanotic heart-disease, and it includes a considerable amount of original work, particularly in relation to the circulation and heart tolerance tests. The section by Eek on embryology is comprehensive and the descriptions good, giving prominence to the second or back torsion of the bulbis cordis, which if increased will produce the components of the tetralogy of Fallot. A grouping of the 114 cases shows that 61 were examples of this condition. The clinical features have been carefully scrutinised, and the investigations, which have become much more exact and exacting as a result of the possible surgical implications, have been carried out in detail; the results in different types of heart lesions have been tabulated and described. The chapter on radiology and cardioangiography is particularly well illustrated and the X-ray reproductions are excellent. Surgical treatment has followed the Blalock-Taussig principle, using chiefly the anastomosis between subclavian and pulmonary arteries. Of the 21 patients operated on, 8 died; but the results were good in the survivors. A footnote comments on the usual experience of a high mortality only in the early cases: this is borne out by survival after 12 of 14 subsequent operations. The advantages of experienced team-work are once again shown.

The Surgical Treatment of Facial Injuries

VARAZTAD HOVHANNES KAZANJIAN, M.D., D.M.D., professor emeritus of plastic surgery, Harvard University; JOHN MARQUIS CONVERSE, M.D., associate professor of clinical surgery, New York University. Baltimore: Williams & Wilkins. London: Baillière, Tindall, and Cox. 1949. Pp. 574. 76*s.* 6*d.*

Dr. Kazanjian and Dr. Converse (both well known in this country as well as in the U.S.A.) have combined to produce a fine book on the treatment of facial injuries. An opening chapter on the comparative anatomy of the skull and face is interesting though not fully pertinent: chapters on the histology and pathology of wound healing, and the early treatment of facial injuries are more valuable, and from the long section on fractures of the mandible, maxilla, nose, and zygoma, many useful and practical points can be learnt. But the repair of soft tissues inevitably occupies most of the book, and all the methods in common use are described—local flaps, free grafts, and grafts from a distance—with diagrams and photographs illustrating special problems. Deformities of the nose and of the jaws are well handled. Temporomandibular ankylosis, facial paralysis, ear deformities, and burns of the face have a chapter each, with final chapters on the use of prostheses and the management of anæsthesia. The book could be studied with advantage by all concerned with this type of work.

Clinical Management of Varicose Veins

DAVID WOOLFOLK BARROW, M.D. London: Cassell. 1949. Pp. 155. 25*s.*

Dr. Barrow, of Lexington, Kentucky, says of his small book that "this monograph is the result of personal observations of 2500 patients": and certainly the text reveals continued, fresh, and thoughtful experience. Moreover, though his references are few, many of his quotations show wide reading.

He limits his account of anatomy to that of the saphenous and communicating veins. More about the deep veins and the alternative anastomotic channels through the gluteal and pelvic vessels would be helpful; and though he gives the embryology and variations of the short saphenous vein, he omits detailed landmarks to help those exposing the saphenous veins at the ankle and above and below the knee. The appearance of varicose veins early in pregnancy, before the uterus can cause mechanical obstruction, may be explained by the fact that flow from the internal iliac veins is increased by thirty-two times the normal amount and they thus become large enough to obstruct the discharge from the external iliac vein. Barrow reports the finding of Beecher that the pressure in the normal internal saphenous vein at the ankle when walking is 20–75 cm. of water, but that when the vein becomes varicose the pressure rises to 95 cm. Even so, œdema does not necessarily develop, because the deep veins, if competent, draw off the blood. When the deep and perforating veins are incompetent, œdema of the foot, ankle, and leg follow—a significant diagnostic point. In treating varicose veins of the long saphenous system Barrow gets good results from its ligation and stripping, followed by postoperative injections given ad infinitum. He emphasises that precise diagnosis is essential, for 32 % of his patients had already had an ineffective operation for their varicose veins.

This is a splendid book. The forthright opinions are supported by the author's statistics and those of other experts. The principles of his practice are in accord with the best in Britain, and can be adopted in every surgical clinic.

Thorpe's Dictionary of Applied Chemistry (4th ed. Vol. IX. Oils, fatty—Pituitary body. London: Longmans, Green. 1949. Pp. 671. 80*s.*).—This volume opens with an authoritative treatise on the natural fats, by Professor Hilditch, and ends with a brief account of the hormones of the pituitary gland; and in between are many subjects of interest to the doctor and biologist, including vitamin P, pantothenic acid, penicillin, patulin, and opium. Several articles deal with physical matters of importance to both the physiologist and biochemist—such as osmotic pressure, oxidation-reduction potentials, and pH. Oxidising enzymes, photosynthesis in plants, pest control, photography, and petroleum are perhaps not too strange as bedfellows; while perfumes, synthetic, and onion lend fragrance to a volume which is in every way up to the standard of its predecessors.

Introduction to Neuropathology (New York and London: McGraw-Hill. 1950. Pp. 494. 85*s.*).—Dr. S. P. Hicks and Dr. S. Warren, of Harvard, have produced a good textbook of elementary neuropathology, of the sort that medical students like. There are plenty of excellent photomicrographs; there is not too much text; pedantic details are omitted; the typescript is large and clear; and the paper is thick and shiny. Throughout there is a pleasant link between clinical neurology and pathology, achieved by brief references to what has happened to the patient. The chapter on cerebral tumours, which takes up a quarter of the book, is particularly lucid, though it is a pity that the text must have been completed before Kernohan's simplified classification of the gliomas was published. The older nomenclature is used, but the illustrations prevent any confusion. As so often with well-presented American texts, the only deterrent to purchasers is the price.

Clinical Radiation Therapy (2nd ed. London: Henry Kimpton. 1950. Pp. 902. £5 5*s.*).—Prof. Ernst A. Pohle, as editor of this textbook, now musters a company of 20 expert contributors. Ovid O. Mayer, writing on diseases of the blood and blood-forming organs, includes a description of the use of radioactive phosphorus in the treatment of the leukæmias, and Gordon Richards gives a thoroughly useful account of radiation therapy in diseases of the respiratory system and breast. The techniques described are modern, and the diagrams show exactly how they are applied, with dosage in terms of röntgens received at the tumour. The section which deals with the breast brings together much important information, both clinical and technical. It is surprising, however, to find no chapter dealing with radiation treatment of diseases of the mouth and pharynx: this method of treating these important cancers is mentioned only in the section on the use of low-intensity radium needles. On the other hand, a complete section is devoted to radiation treatment of diseases of the gastro-intestinal tract, various techniques for the irradiation of cancer of the stomach, including the use of radon gold seeds, being described, with a table showing the number of millicuries to deliver to masses of various diameters, dosage being specified in terms of skin erythema dosage. Treatment of diseases of female genital organs occupies a long and elaborate section in which methods of treating cancer of the cervix in most of the important centres are reviewed, but the descriptions are not always completely accurate. Tumours of the genito-urinary tract, and diseases of the nervous system, eye, ear, connective tissue, skin, and glands of internal secretion, all receive due notice. Though the clinical accounts of diseases are usually good, many conditions are included for which radiotherapy is of doubtful value, and space which might have been used to discuss some of the newer developments is still given to old techniques.

THE LANCET

LONDON: SATURDAY, JUNE 17, 1950

Drugs in Parkinsonism

The symptomatic relief obtainable with drugs of the belladonna group in most cases of parkinsonism has been recognised for many years; for, according to Mendel,[1] the value of hyoscine in this condition was noted by Gnauck in 1882. Atropine, hyoscyamine, preparations of stramonium, extract of Bulgarian belladonna in white wine, and sundry proprietary preparations of the solanaceous alkaloids were introduced later. In general, the effects of all these drugs are similar, but their relative efficacy seems to vary from patient to patient. To get the best results with any of them the dosage must be pushed to the limit of tolerance, where side-effects begin to appear. In patients with sialorrhœa the usual reduction in salivation is desirable, but in other cases dryness of the mouth is often troublesome. Paralysis of visual accommodation is also common, and drowsiness, dizziness, and even hallucinations may occur. For each patient it has to be decided whether the benefit obtained is enough to offset these disadvantages.

In the last few years many other drugs, most of them synthetic, have been tried in parkinsonism. Curare, which mainly acts at the myoneural junctions, will reduce or even remove the rigidity and tremor, and apparently somewhat before it paralyses voluntary movement.[2] However, owing to the difficulty of separating these two effects and the inconvenient necessity for injecting the drug, it is not used in parkinsonism. The synthetic relaxant mephenesin ('Myanesin'), though it will also paralyse voluntary muscle, has a different mode of action, mainly exerted on the interneurones of the spinal cord and brain-stem.[3] It has little effect on the higher centres. When given intravenously in parkinsonism it can reduce the rigidity and tremor without affecting voluntary power [4] and with no atropine-like effects on salivation or accommodation. It may cause giddiness, but this is usually not severe, and the vomiting that has been reported is uncommon. As with curare, however, intravenous injection is tiresome, and the relief so obtained is transitory; administration by mouth produces less consistent though longer-lasting results. More serious disadvantages of mephenesin are that an overdose may cause respiratory paralysis for which there seems to be no effective antidote, and that intravenous injection may cause intravascular hæmolysis. None the less, the work done on mephenesin has established that it is possible to relieve the symptoms of parkinsonism without producing atropine-like side-effects.

The remaining substances to be considered do not attain that ideal, but they have much less effect on salivation and accommodation than the solanaceous drugs. Each has been introduced to clinical medicine as the most therapeutically active member of a series of related compounds, and all possess, to a greater or lesser extent, anti-histamine and local anæsthetic properties. (All the substances that are effective in parkinsonism, including atropine and mephenesin, are local anæsthetics, but the fact seems to be of no particular significance.) They are all of undoubted value in parkinsonism, yet each has its individual peculiarities. With 'Parpanit' [5]—a compound closely related to the synthetic antispasmodics 'Trasentin' and 'Dolantin'—the common side-effects are giddiness and a feeling of lightness of the limbs. 'Diparcol' [6] may produce depression and paræsthesiæ. With 'Benadryl' [7] drowsiness is common, and paræsthesiæ and dizziness occasionally occur. 'Artane,' a clinical trial of which was lately reported by Ellenbogen [8] in these columns, has sometimes caused mental confusion and headache. Of these four drugs, diparcol is perhaps the most liable to cause side-effects; but some patients seem to do better with it than with any other treatment. Parpanit, which also produces a high incidence of side-effects, is more often successful, though the improvement may not last long. For best results with either of these substances the dosage must be carefully adjusted to suit the patient. The drowsiness from benadryl can be avoided by giving amphetamine sulphate at the same time. Artane is probably freest from undesirable effects, and, as with benadryl, there is less need to find the exact dosage for each patient. Any of these drugs may be given at the same time as the patient's usual solanaceous medication. As Dr. J. Phillips and two colleagues say in their letter on another page, stopping stramonium sometimes leads to unpleasant withdrawal symptoms. When a change of drug is being made it is usually wise to give new and old together for a time and make the replacement gradual. At the Highlands Hospital in North London artane has given good results in 28 out of 35 postencephalitic cases, with remarkable freedom from side-effects, but Dr. Phillips mentions the "prohibitive" cost of the drug and its present scarcity.

The improvement obtainable with any of the drugs now used in parkinsonism is limited. On the whole, rigidity (as it affects ease of movement) is more readily relieved than tremor; and speed of movement is not likely to be much altered. Even in the most satisfactory cases the signs of the disease remain, and indeed the improvement is often wholly subjective. At best, the patient is not restored to complete normality of behaviour. But, apart from the efficacy of the drug prescribed, there are other important factors affecting the outcome. As KINNIER WILSON[9] pointed out, every activity is more of an effort for the patient with parkinsonism than for his healthy fellow, and the temptation not to make the effort is constantly with him. Thus he may—and often does—fail to perform many actions of which he is physically capable. For this reason, a drug which only slightly facilitates the patient's movements may yield dramatic results by giving him new confidence and enthusiasm. On the other hand, when the patient's activity has long been severely restricted, his musculature will be weak, his posture bowed, and his joints stiff, and no drug can then produce much immediate improvement. In such cases reablement by graduated physiotherapy may be of great benefit. Better still, the physiotherapist should be called on to prevent physical deterioration developing; and helping the patient to retain his physical powers will ensure that neglect and despair are not allowed to determine his future.

Cerebral Aneurysms: Congenital or Acquired?

PATHOLOGISTS have long been puzzled by the frequency of non-inflammatory aneurysms on the circle of Willis and its main branches. In 1890 NEWTON PITT[10] reported the finding of 23 cases in 9000 necropsies, an incidence of 0·25%. OSLER[11] noted 12 cases in 800 necropsies (1·5%), and most writers quote figures between these extreme values. In the general population, therefore, something like 1 person in 200 has one of these cerebral aneurysms. As regards cause, the most obvious non-inflammatory lesion leading to weakness of a vessel wall is atheroma, and several writers emphasise the importance of atheroma in the genesis of cerebral aneurysms. TURNBULL,[12] however, in a study of 30 such aneurysms, found atheroma absent or slight in 21 of the cases, of which 17 showed little or no cardiovascular hypertrophy. He therefore suggested that there is an additional factor, probably an inherent weakness due to a congenital abnormality in the structure of the arteries at their points of junction. This suggestion seemed to be strongly supported by FORBUS[13] when he demonstrated small gaps in the musculature of the media at the points of bifurcation of the cerebral vessels in a case of multiple aneurysms of the circle of Willis.

Atheroma in a congenitally weak vessel was a satisfactory solution until GLYNN[14] pointed out that these muscular defects in the media can be found in the cerebral vessels at necropsy in about 80% of cases without cerebral aneurysms. Moreover, in each case where the defects were found they were present in about 80% of the 15 different branches examined. Thus, on the average, four cases out of five show defects in 12 out of the 15 main bifurcations in their cerebral arteries. GLYNN justly contended that a theory which ascribes major significance in the ætiology of a condition occurring in 0·5% of the population to a factor present in about 80% of th population must surely be overlooking some mo significant factor. Since freshly removed cerebr vessels with natural and artificial muscular defect but with intact internal elastic membranes coul withstand inflationary pressures of 600 mm. Hg, h concluded that the maintenance of form in the vessels is not a function of their muscle but depend on the integrity of their elastic tissue; in his vie aneurysms arose on a basis of elastic degeneratio and congenital muscular defects played no part i the ætiology.

CARMICHAEL[15] has now tried to reconcile the tw views. Thirteen aneurysms which he studied in detai all showed evidence of considerable degenerativ disease in the intima, and the age-incidence in 26 published cases also favoured the degeneration hypothesis. On the other hand, the virtually constan relation of the aneurysms to the arterial bifurcations, where developmental defects occur, seems t warrant the view that developmental deficiency is th one essential basic lesion. CARMICHAEL therefor suggests that a breach in both layers is necessary, th muscular breach being usually a congenital defect whereas the elastic breach is the result of atheromatous degeneration. But the original difficulty still remains of reconciling the frequency of the defects with the rarity of the aneurysms, and CARMICHAEL offers several interesting suggestions to account for it. First, two independent lesions—congenital defect in the media and elastic degeneration in the intima—must coincide. Secondly, the defects in many cases are too small. Thirdly, atheromatous degeneration is often preceded by elastic hyperplasia, and there is also considerable variation in the time-relationship between elastic degeneration and fibrohyaline thickening in atheromatous plaques. It is presumably only in those cases with precocious elastic degeneration that the intima is sufficiently weakened to allow aneurysm formation These three reasons may well account for part of the discrepancy between the incidence of aneurysms and defects; but are they really adequate ? To take them in turn, the coincidence of two common occurrences will itself be quite common. Atheroma is not only an extremely common degeneration in people over 30, when the great majority of aneurysms occur, but it also shows a special predilection for vascular bifurcations and the mouths of branches, apart from any underlying medial defect.[14 15] Coincidence of the two lesions must therefore be extremely common and in later life almost as frequent as the defects themselves. The size of the defect might well be important, but CARMICHAEL himself admits that probably one defect in four is large enough to be effective; this means that, in four people out of five, 3 of the 15 bifurcations examined by GLYNN would present adequate defects. The third suggestion—that the fibrohyaline thickening associated with atheroma compensates in many cases for the elastic weakening —is probably valid and may account for the relative rarity of these aneurysms.

Medial defects of the kind described by FORBUS are by no means confined to the cerebral vessels, for he observed them both in the coronary and mesenteric vessels in 2 out of 9 specimens in each case. Atheroma also by no means rare in these other vessels, and ; non-inflammatory aneurysms are very seldom ind in them. The striking difference in the incidence aneurysms between the cerebral and other vessels obably depends on the different distribution of ir elastic tissue, which is mainly adventitial in most scular arteries and almost entirely intimal in the ebral vessels. In the intima the elastic tissue is rticularly liable to degenerative changes, whereas in adventitia it remains virtually unaffected. Thus Carmichael maintains, aneurysms may well m only when there has been a previous breach in th the muscle and elastic layers, but the evidence licates that the muscular defects do not predispose elastic degeneration.[14] There is no such definite idence with regard to the reverse situation, and the al effects of loss of elastic tissue may well lead to rophy of the underlying muscle. Moreover, it is clear m inflation experiments that the elastic layer alone is pable of maintaining the form and integrity of the ssel wall. The essential factor in aneurysm forma- n must therefore be a breach in the elastic tissue, and this sense the congenital medial defect is relegated secondary importance. The medial defect may be sential for the development of this type of aneurysm, it since it is almost ubiquitous in the cerebral teries it can only be regarded as a secondary, even essential, factor. Hence the rarity with which ese defects lead to aneurysms in non-cerebral teries.

Anti-histamine Drugs in Colds

In his third Dunham lecture at Harvard last year, r. C. H. Andrewes, f.r.s.,[1] remarked that "even ie most eminent men of science almost invariably se all sense of critical judgment when colds and pecially their own colds are concerned, and the atistical methods they use in their daily work are ll forgotten." For those who seek to appraise a emedy objectively, the way is hard. In the first lace, it is often difficult for the patient—and just bout as difficult for the doctor—to tell whether the ymptoms are really those of a common cold, articularly at the onset. Then immunity varies, s also does the natural course of the disease; and ince the disorder is slight, and normally does not ring the patient to a doctor at all, attempts at omplete follow-up will often be thwarted. Further- iore, the patient—and his physician—may be ifluenced psychologically by the remedy under trial. Diehl[2] found that 35% of patients with colds who eceived lactose reported good results.)

These impediments may account in part for the elay in the publication of controlled studies of anti- istamine drugs in this disease. The first, encourag- ig, report appeared in 1947[3]; and thereafter this roup rapidly won public favour, particularly in the .S.A. Last year, however, workers at the National nstitute of Medical Research[4] described a small, ut carefully controlled, investigation indicating that t least one drug in the group is valueless against he cold; and now this conclusion is reinforced by two arger studies made in the U.S.A.

One of these was undertaken at Cleveland, where Prof. J. H. Dingle and his associates[5] have been continuing their war-time work on acute respiratory disease. Their investigation was made in two ways. First, they have under continuous observation a population of families whose natural illnesses are reviewed clinically and in the laboratory; and because a number of these families began to take anti-histamine drugs for colds, all were asked to note the drug used. Thus complete records were obtained of dosage and clinical effects in those individuals who took these substances, and in those who did not (who acted as controls). Altogether 87 treated and 289 control illnesses (75% in each group were classed as colds) were observed in 203 people. The drugs used were a mixed bag, but thonzylamine hydrochloride and chlorprophenpyridamine maleate were employed in 55 and 13 of the illnesses. Taking full account of whether dosage was rated as adequate, those who took the anti-histamines fared no better than those who did not; and this was true also of 32 subjects who had two or more colds at least one of which was treated with an anti-histamine substance. In the second investigation the treated members of a group of volunteers who received an intranasal inoculum of secretion from a case of common cold were given pyrathiazine hydrochloride or thonzylamine hydrochloride, 50 mg. four times a day, administration being started before the inoculation and continued for five days. The treated were no better off than the controls in the incidence, severity, symptoms or duration of colds.

The second report, by Hoagland and his colleagues,[6] concerns 190 patients in the U.S. Army. These were divided into five groups according to whether they received tripelennamine hydrochloride orally, the same drug by nebuliser, chlorothen citrate orally, or one of two inert substances. Of the patients who were given an anti-histamine drug orally (50 mg. five times daily), 16% reported cure within twenty-four hours, while among those receiving placebos by mouth or nebuliser the percentage was 27; and the percentage was much the same as this for those receiving tripelennamine hydrochloride (0·5%) by nebuliser. The results were little different when those who began treatment within twenty-four hours of the onset were considered separately. The one advantage which some of the treated group seemed to gain was decrease of the irritating serous nasal discharge in the initial phase—an effect that is probably bound up with an allergic response to the cold virus.[7]

Self-medication with the anti-histamine compounds has its dangers;[8] and in the U.S.A. warnings have been issued[9] and their control has been mooted.[10] The Medical Research Council is investigating fully their place in the common cold.[11] Meanwhile, the public should know that probably the best that these drugs can offer—and even this not always—is a little easement for a few hours while the cold is getting under way.

Annotations

TREATMENT OF OFFENDERS

THE Home Secretary's Advisory Council on the Treatment of Offenders has been considering the borderland between sanity and insanity, and what should be done with offenders who inhabit this borderland. Their conclusions are published on p. 1123. In brief, they are in favour of a special penal institution for the mentally abnormal criminals who are not insane. Those guilty of less serious crime, who are willing to undergo treatment, should be dealt with by probation and outpatient psychiatric treatment under Section 4 of the Criminal Justice Act. In 1939 Norwood East and Hubert[1] advised that the minimum period of imprisonment in which psychotherapy could be of any help was four months (i.e., a six-month sentence with the usual two months' remission) and Prison Commission experience confirms this. Since the maximum period of psychiatric detention should not be longer than the maximum legal sentence for the particular crime, no crime meriting less than six months should be rewarded by treatment in the special penal institution. Though quarter sessions and assize courts should pronounce sentence to the institution, the power of admission would in fact rest with the psychiatrists of the Prison Commission. No court would be permitted to pronounce such a sentence without a report from the commission on the prisoner's mental state, and the commission would have the right to reject in advance any candidate on the grounds of unsuitability. Further, the commission would have power to transfer appropriate prisoners from ordinary prisons to the new institution.

Wisely, the council makes no attempt to define the psychiatric clinical types who would be collected. There can, however, be little doubt that many would be psychopaths of the most difficult kind. How far physical and psychological therapy is able to assist such people is something we can only find out by trying. The council's proposals are well designed to collect all whom the Prison Commission desire to be drawn into the net, and to exclude the unsuitable. Though such an institution will have more in common with a hospital than a prison, it must clearly be run on maximum security lines. If it is too pleasant, and if release is often quicker than from an ordinary prison, we shall get every defending counsel with a hopeless case trying to prove his client a psychopath. Danish experience[2] suggests that the only hope for the criminal psychopath is the indeterminate sentence—that unless the psychopath is forced to try to change himself, as a condition of release, he does not do so. On this, the council hedge; though treatment may require a longer time than the maximum legal sentence for the particular offence, they feel that they would not carry public opinion with them in proposing more than the existing maximum.

Only experience can show whether the absence of this provision is as fatal to success as the Danes maintain. The proposals for the collection of psychopaths are an advance on Danish law. It remains to be seen whether we need more than an institution to achieve the Danish 50% recovery-rate.

There is one further practical point. If the Prison Commission is to provide reports of any value before sentence, the accused must be remanded in custody. At present, some accused persons are reported on to higher courts, with regard to their suitability for Borstal or corrective training, by prison medical officers and governors who have never had an opportunity of seeing them.

VIBRIO FETUS AS CAUSE OF HUMAN ABORTI

BECAUSE of the attention given to *Brucella abo* as a cause of human infection one is apt to forget t this is only one of the many organisms known to prod infective abortion in cattle; nearly forty years M'Fadyean and Stockman[1] drew up a list of th which might be found. Among these was the *Vib fetus ovis*, which has hitherto been looked on as pat genic to cattle and sheep, though the infection of th animals is widespread in only Europe and the U.S Evidence is now accumulating that the infection can transmitted to pregnant women and that its abortifaci action is in many respects similar to that in anim Whether men can also be infected is uncertain, but a c of ankylosing arthritis in Paris suggests that pregnan is not essential for infection. This case is cited Vinzent and colleagues in their vivid account[2] of th further cases seen since the first description of t human disease[3] in 1947.

The infection affects women in the later months pregnancy and takes the form of an acute septicæm The diagnosis is made by blood-culture, the m satisfactory culture medium being citrated meat pepto broth containing 1% gelatin, since morphological the organism resembles *V. choleræ*. After an invasi period of about 24 hours, a severe illness develops wi intense headache, remittant fever, and a fleeting pne monia; nevertheless, the patient's general conditi remains good. There is a well-marked secondary anæm and a moderate leucocytosis with about 80% polymorph After an illness lasting up to 4 weeks the sympton disappear, usually with spontaneous expulsion of th uterine contents. Oddly enough, it may be possible t obtain a viable infant; the explanation may be tha the infection is mainly a "placentitis," and the histo logical findings certainly substantiate this view. Th placenta, whether human or in animals, is characterise by a patchy necrosis associated with an infective throm bosis of the arteries supplying the affected cotyledons and the infection clears up rapidly once the placenta i expelled. Normal conception is possible subsequently The pathogenicity of the infection, judged by fatality rates, may not be high, but it can produce an alarming illness while it lasts. Serological changes persist for less than a year after the infection and are specific to the particular strains of *V. fetus*, so agglutination reactions should be performed with multiple strains.[4] In future it may be worth while to include *V. fetus* in the routine series of serological tests applied to patients with obscure fever. As regards treatment, clinical improvement seems to follow a dosage of 400,000 units of penicillin daily together with one of the more active sulphonamides. *V. fetus* is fairly sensitive in vitro to both penicillin and streptomycin. German veterinary surgeons have claimed good results in cattle with neoarsphenamine, and this drug might well be tried in human cases.

How human infection occurs is unknown but it is reasonable to suppose that the bovine organisms might be spread by dairy products. Cattle can certainly be infected by mouth. All attempts to culture the organism in milk have been unsuccessful and no-one knows how long a previously infected cow may remain contagious. It is somewhat remarkable that of the three French cases described by Vinzent et al.[2] one was in the wife of a doctor and one in a midwife. So far, no human cases have been reported in Great Britain, but this may be because they have not been looked for. There

4. According to its most recent list (1948), the National Collection of Type Cultures maintains 3 strains of *V. fetus*.

are still some severe septicæmias that defy all attempts at exact diagnosis. And it might be profitable to find out whether *V. fetus* infection takes any part in the causation of that 25% of all abortions which are said to be unexplained.

MEDICAL PATENTS

AMONG doctors the habit is to share knowledge freely: what is learnt by one is made known to all. Desire to preserve this open communication and to avoid harmful monopolies underlies the precept that no medical man should take out a patent in respect of a medical invention. In abstract this is a sound, and even a noble, idea; but in the context of a warmly competitive world market it has proved increasingly detrimental to those whom it is meant to protect—the public. Accordingly, in their annual report[1] the council of the British Medical Association recommend that, subject to certain conditions, a doctor should be allowed to patent an invention.

Patentable discoveries derive from the work not of clinicians but of research-workers, who nowadays are associated with chemists, physicists, engineers, and others. A special committee which the council appointed, with Dr. Robert Forbes as chairman, notes that "there immediately arises the possibility of a moral obligation upon the non-medical specialist to avoid patenting where formerly he would have patented, and it may be incumbent upon the medical profession to make concessions in departing from the custom that formerly prevailed." There are further, and perhaps weightier, arguments for a change of attitude. Where an invention is not protected by a patent, a manufacturer would normally refuse to handle it, lest others took the opportunity of profiting freely by his development of the discovery. More important still, observance of the no-patenting rule may tell hard on the whole country, particularly where a "central" patent is vacated: the British consumer now pays royalties to American firms for penicillin manufactured in this country.

Some years ago the British Medical Association proposed that doctors should be enabled to dedicate patents to the public. There are precedents for such usage. The Dicks patented their scarlet-fever toxin and antitoxin, but delegated their rights to a special committee. The patent for Sir Frederick Banting's process for preparing insulin was taken out in the name of the University of Toronto, but the British rights were vested in the Medical Research Council. The way to delegation in the public interest has now been opened by the Development of Inventions Act, 1948, under which the National Research Development Corporation was set up as an independent body to which medical patents might be assigned. As regards reward to the inventor, none would be paid by the Corporation to anyone who is another man's servant—for instance, a Crown servant, who in any event would be precluded by his contract from deriving any benefit from his invention (though he might receive an award from the Departmental Awards Committee). The relationship between the corporation and a sole worker not employed by an organisation who wished to assign a patent and claim an award would be one of buyer and seller; but, says the B.M.A. report, "in the case of a medical man the Corporation would not take any action that would conflict with a policy laid down by the profession as a whole." When the association's Representative Body meets next month it will be asked to approve the conclusion that "in the opinion of the Association there is no longer any objection to the patenting of inventions for which members of the medical profession are responsible, provided such patents are assigned to the National Development Corporation with a view to their administration in the best interests of the public as a whole." This seems a realistic solution.

THE THYROID AND LACTATION

THE lactation-stimulating (galactopoietic) effect of thyroid-active preparations seems to have been first suggested in 1896 by an experiment of Hertoghe,[1] who increased the milk yield of a cow by feeding it dried thyroid gland. This effect of dried thyroid was later independently rediscovered and extended to thyroxine by Graham,[2] and soon the results of Folley and White[3] in lactating cows clearly demonstrated the considerable galactopoiesis produced by injections of crystalline thyroxine. Interest in the possible applications of this discovery in dairy farming remained lukewarm for some years, mainly because of the belief that the effectiveness of thyroxine by mouth was so low that it would be uneconomic to give it to milking cows except by injection, which would obviously be impracticable. And dried thyroid gland, though fully active by mouth in cows, was not plentiful or cheap enough to be a practical alternative. At the beginning of the late war, however, Ludwig and von Mutzenbecher[4] discovered that a thyroid-active protein effective by mouth could be prepared by the iodination of casein. Improved methods of cheap large-scale production were soon devised, so that extensive researches could be begun on the various uses of this artificial thyroid-active protein in agriculture, mainly for increasing the milk yield of cattle, but to a less extent for stimulating egg-production in hens and accelerating growth in young pigs.[5]

Lately the wheel has come full circle, bringing synthetic thyroxine back into the picture. A new synthesis of *l*-thyroxine has been worked out[6] which seems capable of large-scale development so as to supply the synthetic hormone in considerable amounts at relatively low cost. Following this, Bailey, Bartlett, and Folley[7] have shown that *l*-thyroxine by mouth is a good deal more active in stimulating lactation in milking cows than has hitherto been believed. The optimum oral dose of the synthetic hormone for this purpose (about ten times that by the subcutaneous route) is such that, in view of its relatively low cost of production by the new method, it is likely to be at least as cheap to use as iodocasein, and in practice it has some important advantages. Thus, the crystalline *l*-thyroxine is virtually tasteless, whereas iodocasein preparations are often so unpalatable that a significant proportion of cows will refuse to eat rations containing them. Perhaps its most valuable feature is that, being a pure crystalline substance, it does not need to be standardised by bio-assay, a troublesome and unsatisfactory procedure which has proved difficult from the very outset of the experiments with iodocasein in this country. Provided the long-term experiments now in progress under the auspices of the Agricultural Research Council show that the repeated administration of thyroid preparations in successive lactations does no harm to the health or reproductive abilities of the cattle, synthetic thyroxine is likely to be chosen for general use.

The thyroid treatment of hypogalactia in women also dates back to Hertoghe, but the modern clinical investigations can be said to have started with the work of Robinson,[8] who reported successful though variable results in hypogalactia by feeding either dried thyroid gland or thyroxine. The value of thyroid treatment has recently been demonstrated in France by Romani et al.[9], who confirmed the effectiveness of crystalline thyroxine by mouth in women, and by Roche et al.[10] with iodocasein. These successful results will no doubt be followed up, but in view of the advantages of synthetic thyroxine enumerated by Bailey et al. there does not seem to be much point in further studies with iodinated casein or even dried thyroid gland. Robinson [11] implied that in the cases she investigated the hypogalactia was due to under-production of thyroxine stemming from a latent iodine deficiency becoming manifest under the stress of lactation. On this basis she treated hypogalactia with Lugol's iodine solution, but her favourable results have not been confirmed [12]; in any case, what is known about the relation of the thyroid gland to lactation [13] lends little support to the iodine-deficiency view.

THE BIRTHDAY HONOURS

With eight new knighthoods the list of doctors in the Birthday Honours is longer than it seemed at first sight, and it contains many notable names. Mr. Arthur Porritt, who as chairman of the Empire Games Federation is appointed K.C.M.G., is well known as an athlete, a surgeon, and a soldier, and very well liked in all capacities. As K.B.E. the heads of the medical departments of the Royal Navy and the Royal Air Force, Vice-Admiral Greeson and Air Marshal Livingston, are joined with Prof. Hamilton Fairley, F.R.S., one of the most respected figures in tropical medicine, who served the Services so faithfully during the war. Of the four knights bachelor, one, Dr. W. S. Newton, belongs, like Professor Fairley, to Australia, where he is physician to the Alfred Hospital, Melbourne. Dr. A. N. Drury, F.R.S., whose administrative talents were discovered only by the war, has proved himself a most happy choice for the directorship of the Lister Institute in its time of growing activity. Prof. Geoffrey Jefferson F.R.S., besides the specialised knowledge that has earned him his new facilities for neurological surgery at Manchester, has a strength and wisdom that give him wide influence. And finally Professor Spence, of Newcastle and the University Grants Committee, has a flow of ideas—always arresting and often strangely right—which makes him one of the most valuable members of our profession. The other appointments to orders are for equally various services—important and often unobtrusive—which it is good to see occasionally recognised in a formal way.

SERVICE DOCTORS' PAY

To explain the Army's difficulties in finding enough doctors one need go no further than the Government's statement on defence,[14] which says: "a high level of recruitment cannot be expected unless Service conditions compete in attractiveness with those of civilian life." Professionally the conditions are far more attractive than is often supposed. As General Cantlie told the West London Medico-Chirurgical Society the other day, the Army in peace-time is responsible for the medical care of 400,000 men, women, and children. Its hospitals now admit civilians when they have room, and last year 7000 operations were performed in them, not to mention 5000 deliveries of soldiers' wives in Army family hospitals. The service offers opportunities not only of working, but also of training, in a specialty, and of 90 officers studying at Millbank since the war no fewer than 74 have obtained higher diplomas. Professionally, indeed, the prospects in a Service career are probably better than ever before; and, now that the post-war revulsion of feeling against military life is diminishing, the Army would no doubt enlist many young doctors, provided it could also offer them adequate pay. But that is just what it cannot do.

So long as the Treasury refuses to let Service remuneration "compete in attractiveness" with that of civilian doctors, the Army is forced to rely more on compulsion than attraction. As the establishment of regular and short-service R.A.M.C. officers is 37% below strength,[15] it depends for general-duty officers on conscription, which applies to doctors up to the age of thirty. This, however, is only a partial and temporary solution of the problem, for an increasing proportion of newly qualified doctors have already performed their National Service, and in 1952, Lord Webb-Johnson says, there will be a shortage of about 500 medical officers in the Army alone.[16] If that seems a distant difficulty, the lack of specialists, on the other hand, is very present and pressing. The Army has only about two-thirds of the number it requires, and, since conscription of doctors up to thirty years of age does little to bring in experienced specialists, it has been obliged to advertise for civilians to fill the more serious gaps. Meanwhile it has continued—for doctors and dentists only—the war-time ban on the retirement of officers.

This situation is thoroughly unsatisfactory. For well over a year the British Medical Association has been making representations,[17] and at one time it seemed almost certain that action would be taken; but the discussions held with the Defence departments in January and April proved fruitless because the Chancellor of the Exchequer is frankly less concerned with the efficiency of the Government services than with maintaining the wage-freeze. As in the case of Civil Service doctors, what is really needed is not a concession here or there by the Treasury, but an unprejudiced examination of the facts, in the light of which the Government can decide its policy. When a similar situation arose in the R.A.M.C. after the war of 1914–18, a Cabinet committee was eventually set up, in 1925, to inquire into medical remuneration in the Services; and such an investigation should be made again now. Unfortunately in 1925 this procedure was not adopted until the B.M.A., alleging breach of faith by the Government, announced that it would no longer publish in its journal any reference to the terms and conditions of service in the R.A.M.C. Doubtless having this precedent in mind, the B.M.A. has formally stated that it will accept no more advertisements for civilian specialists for the Army at higher rates of pay than those of the corresponding regular officers.[15]

Though the practice of reinforcing the Army medical services by employing civilian specialists is not in itself unreasonable, and though the payment of rather higher rates for such temporary appointments can also be defended, the combination of underpayment in the service, a ban on retirement, and the importation of civilians at considerably higher remuneration seems to us intolerable. The ban on retirement puts this affair in a different category from that of the Civil Service doctors; and though, as an independent journal, we are, for reasons stated,[18] averse from refusing advertisements for Government appointments, we shall feel obliged to refuse those of the Army unless the ban is lifted in the near future or a proper inquiry is instituted.

TREATMENT OF OFFENDERS

REPORT TO THE HOME SECRETARY BY THE ADVISORY COUNCIL ON THE TREATMENT OF OFFENDERS *

THE Council has been considering whether any practical steps can be taken to provide both the courts and the administration with better means of treatment for offenders who, although not certifiable as insane or mentally defective, show abnormal mental characteristics. We have taken evidence from the Prison Commissioners, the Board of Control, and from Dr. Denis Carroll who has had considerable experience of the treatment of persons who have displayed deviation from normal standards of behaviour.

THE LAW

Under the present law an adult offender who is mentally abnormal may be dealt with: (1) under the Mental Deficiency Acts if he is certifiable under these Acts; (2) by being found by a jury to be guilty but insane or insane on arraignment; (3) by being certified as insane after conviction; and, (4) when section 24 of the Criminal Justice Act came into force, by a court of summary jurisdiction making a reception order on evidence that he is certifiably insane. In a number of cases, however, where there is an element of mental abnormality which falls short of certifiable insanity or mental deficiency, the courts have difficulty in deciding how the offender should be dealt with. On the one hand, they are reluctant to commit such an offender to prison with the stigma of criminality and with no reasonable hope of preventing him from repeating the offence and they may desire that he should have mental treatment: on the other hand, they may think detention essential to protect the public and they may consider it necessary to reflect in their judgment public reprobation of the offence. If the circumstances are such that the offender ought to be detained, all the court can do is to commit him to prison and ask the Governor to make a report to the Prison Commissioners on the question whether the offender is suitable for special treatment for his mental state; but after this has been done, the court can take no further action. The evidence before the Council showed that there is no possibility of effecting a substantial improvement in the prisoner's mental state by available psychotherapeutic measures unless he can be detained for a period of at least four months (that is, a sentence of six months); and the Prison Commissioners, after some years' experience, do not now select any prisoners for psychotherapy unless the sentence is at least six months. Where the offence is not a grave one, the courts may be unable or may not think it justifiable to impose a sentence of imprisonment sufficiently long to give reasonable chance of effecting an improvement by psychotherapy: and the only course then open to them is either to bind the offender over, or, if he cannot safely be released, to sentence him to a period of imprisonment which in the particular case is too short for psychotherapy.

The new provisions in the Criminal Justice Act will give the courts wider powers to place offenders on probation, with the condition that they submit themselves for treatment, and while these powers will go far to remove difficulties in the less serious cases they will not enable courts to deal with the offender with abnormal mental characteristics who in the public interest must be treated in custody.

PROPOSED NEW INSTITUTION

The proposal which has been discussed by the Council is that there should be established a new institution other than a prison or a place with penal associations, but something between a prison and a mental hospital, for the reception, observation, and treatment of convicted offenders with abnormal mental characteristics, who are not certifiable as insane or mentally defective. We suggest that the law should be amended to enable a court to make an order for treatment under detention in this institution, the order being quite distinct from a sentence of imprisonment or Borstal detention. Thus, it would be publicly and clearly pronounced that, in the judgment of the court, the circumstances were not of such a nature as to justify the imposition of an ordinary sentence, while at the same time the public would know that the offender was being removed to detention for a period.

The proposal that there should be a special type of institution for these cases is not new. In their Report on the Psychological Treatment of Crime (1939) Sir Norwood East and the late Dr. W. H. de B. Hubert recorded their emphatic conclusion that experience of the necessarily limited facilities for psychotherapy in prisons pointed to the need for a special penal institution for the care, study, and treatment of selected groups of offenders. Its functions would be: (1) as a clinic and hospital where cases could be investigated and, if necessary, treated by psychotherapy and other means, and their disposal decided upon; (2) as an institution where selected offenders could live under special conditions of training and treatment (for example, offenders who proved unsuitable for and unmodified by the influences of the modern prison system); (3) as a colony for the type of offender who had proved quite unable to adapt himself to ordinary social conditions but for whom reformative measures, however specialised, seemed useless, and the severity and hardship of ordinary prison life inappropriate; (4) as an observation and treatment centre for Borstal lads who, because of mental abnormality, appeared unsuitable for or had failed to respond to ordinary Borstal training, and for various reasons were considered unfit for early licence. Dr. East and Dr. Hubert envisaged it as a specialised institution within the prison system; convicted prisoners would be sent there from other prisons under the ordinary powers in the Prison Acts. The report also stressed the importance of careful definition and expert supervision of admission, to prevent the institution being flooded with unsuitable cases.

We understand that the recommendation in the East-Hubert report for a special type of institution has been accepted by the Home Office and the Prison Commissioners (although it has not yet been possible to find or to build suitable premises); but in our view an institution entirely within the penal system will not meet the difficulties which courts experience in dealing with the cases under consideration. The reluctance of a court to stigmatise as a criminal a person who is abnormal is not likely to be removed by the knowledge that the Prison Commissioners might send him eventually to a special type of prison, and we think the East-Hubert proposal as it stands will not remove the sense of frustration at present felt by courts. We have carefully examined how far powers could be given to the courts without the risk of unsuitable cases being sent for special treatment.

We realise that any change in the law relating to an offender's responsibility for his criminal acts would be most contentious. The McNaughten rules have been used by the courts for many years and any attempt to modify them would raise the whole question of the

FIELD, Miss MARGERY FRY, Mr. A. HAWKE, Lady INSKIP, Mrs. CREECH JONES, Mr. J. LEES-JONES, Dr. W. S. MACDONALD, Dr. E. MILLER, Rev. E. SHIRVELL PRICE, Mr. L. RADZINOWICZ, LL.D., the BISHOP OF READING, Alderman R. G. ROBINSON, and Captain H. STUDDY.

medical and the legal view of insanity. It is most important to prevent any impression that persons can commit with impunity offences reprobated by the community. Psychiatry is a young science and evidence from psychiatrists is often brought by the defence in the hope of avoiding the rigour of the law. We think the medical profession would agree with the view that the standard of psychiatric evidence brought before courts is not uniformly high, and it is clear that any change in the law to enable a court, when it has decided that the evidence is consistent with a lesser degree of criminal responsibility, to order treatment in detention would require the most careful consideration. With the development of psychiatric facilities under the regional hospital boards of the National Health Service and the growth of experience in the Prison Medical Service, we think that courts would be able to rely on sound independent medical advice, and we think it important that provision should be made for courts to call for this advice at public expense. Our recommendation is that the court should be empowered, if it thinks fit, after hearing independent medical evidence and any medical evidence brought by the defence, to order detention and treatment in the special institution. A provision similar to that contained in section 4(7) of the Criminal Justice Act, 1948, as to the admissibility of written evidence should be made.

The length of the period which might be so ordered would require careful consideration. On the one hand it must be sufficient to offer reasonable hope of improvement (the time required must largely depend on medical advice and it would not necessarily correspond with the seriousness of the offence) but it must not be of such a length as would be unreasonable having regard to the nature of the offence and the history of the offender; on the other hand, the court would have regard to the protection of the public and the public's view of the iniquity of the offence.

USE OF PROPOSED NEW POWERS

We considered whether the new powers we propose for the courts should be exercisable in such a way as to provide for a longer period of remedial treatment in detention than the maximum period of imprisonment provided by law for the offence with which the court was dealing. There is, we think, no doubt that there are offenders whose chances of eventual reformation have been ruined by numerous short terms of imprisonment when no attempt could be made either by specialised or general training to improve their outlook; and it would in some such cases be in the interests of both the offender and the public if he were required to undergo detention for a period longer than that prescribed by law for offenders who can be regarded as fully responsible for their criminal acts. We think, however, that our main recommendation about treatment in detention in a special institution represents a substantially new conception in the treatment of offenders and that if the Secretary of State saw fit to approve it, it would be more readily accepted by Parliament and public opinion if the new powers of the courts were kept within the existing periods of imprisonment prescribed by law for the particular offence. If the experiment were confined to the more serious type of offence for which a long period of imprisonment would in any case be imposed it would limit the strain on the new institution in its early stages, and in the light of its progress and public opinion after a period, it could be considered whether the new powers should be extended. We suggest therefore that the maximum period of detention and treatment which might be ordered by the court should in no case exceed the maximum period of imprisonment provided by law for the offence for which the person was before the court. We think that the new powers should be confined to courts of Quarter Sessions and Assize and that the discretion should rest in the court and not in th jury.

There would be likely to be some difficulty about th rôle of courts of summary jurisdiction in dealing with this class of offender; for an order for special treatmen in detention would only be imposed after the most carefu consideration of the medical evidence, and this would no always be available for the proceedings before Justices We think it desirable that the Justices should b empowered, when the offence was one with which it wa appropriate to deal, summarily to convict and commit t Quarter Sessions either for sentence or for an order fo special treatment in detention.

The type of institution which we envisage is substantially that proposed in the East-Hubert report, bu with the difference that it should not be regarded as specialised prison within the penal system. In our view it should be removed as far as possible from the prison atmosphere. In addition to the persons who would b committed to it by order of the court, we think the Prison Commissioners should have power to transfer t it ordinary convicted prisoners or Borstal inmates who in the Commissioners' view, were in need of or would benefit from the special and general treatment availabl in it. Conversely, the Home Secretary or the Priso Commissioners should have powers to transfer from the special institution to prison or Borstal persons who wer found to be unsuitable for treatment, and there should b power in the Secretary of State in such cases if it appears to be necessary, in the interests of justice, to recommend remission of part of the period of remedial treatment on the Prison Commissioners' recommendation. Treatment in the special institution should be confined to persons sentenced to prison or to Borstal or persons who, but for the new powers which we propose, would be so sentenced. Young offenders who are seriously maladjusted and require a long period of psychiatric treatment would be treated in a special type of approved school, and not in the special institution. Similarly, it would not be appropriate to send to this institution offenders who could be dealt with under arrangements which will in time be made by the mental-health service. Thus, in the less serious cases where the offender is willing to undergo treatment, he might be dealt with by probation and special treatment under section 4 of the Criminal Justice Act; if he were not a serious menace, but in the court's view required treatment and were willing to go voluntarily, the court could make an order for treatment in a mental-health institution under the mental-health service. This may take time until the mental-health services are developed. The special institution which we propose would be able to concentrate on the more serious cases.

We think that a court should be required, before making an order for special treatment in detention, to take into consideration a special report by the Prison Commissioners as to the offender's suitability for treatment, as is done at present in Borstal cases under section 20(7) of the Criminal Justice Act, 1948. We also think that it should be a requirement that before such an order is made the Prison Commissioners must have signified to the court their willingness to accept the offender in the institution. A similar requirement applies to the committal of mental defectives to the State institution at Rampton, and we are informed that the Board of Control would find it quite impossible to administer the Rampton Institute if the courts had unfettered discretion to send people to it.

We considered whether the classes of person who might be made the subject of a special order could be defined but came to the conclusion that it would be impracticable. We think it is important, however, that some general information as to the possibilities and limitations of psychiatric treatment should be sent to courts, and that if our recommendations are accepted, a working party hould be appointed to prepare notes of general principles or the guidance of the courts.

SUMMARY OF RECOMMENDATIONS

Our recommendations can be summarised as follows :

1. A special institution should be provided by the Home Office or Prison Commissioners for the detention, observation, and treatment of offenders who, although not certifiable under the Lunacy or Mental Deficiency Acts, show abnormal mental characteristics.

2. The Home Secretary or Prison Commissioners should have power to transfer convicted persons from prison or Borstal to the special institution when they are satisfied that they are in need of the special treatment available in it. Conversely the Home Secretary or the Commissioners should have power to transfer from the special institution to prison or Borstal persons found to be unsuitable for treatment ; and the Home Secretary should have power to remit part of the period of detention ordered by the court.

3. Courts of Quarter Sessions and Assize should be given power to order a period of treatment in the special institution : the power should be in the court and not the jury. Where the offence can be dealt with summarily, the court of summary jurisdiction should be enabled to proceed to a conviction and to commit to Quarter Sessions if the Justices are not satisfied with the evidence before them that any of the methods of treatment which they can order are suitable.

4. The new power to order treatment in a special institution should only be exercisable where : (*a*) there has been a conviction for an offence for which the offender is liable to a sentence of imprisonment ; (*b*) the court is satisfied that having regard to the medical evidence the offender is in need of special treatment for his mental state ; and (*c*) the court is satisfied that having regard to the nature of the offence and the need to protect the public it is desirable that he should be detained. The court should have discretion to fix such maximum period of treatment as it thinks proper, having regard to the evidence as to the time required to cure or give a maximum benefit to the mental state, and to the nature of the offence, and the protection of the public.

5. The period of special detention should not be longer than the maximum sentence prescribed by law for the particular offence.

6. The Secretary of State or the Prison Commissioners should have discretion to release the prisoner when they are satisfied that he has obtained the maximum benefit from the treatment. It appears doubtful whether the Home Secretary's present powers to recommend remission of sentences would be wide enough for this purpose, and special statutory provision might be necessary.

7. It is not possible to define the categories of persons who should be subject to a special order. The court should have discretion to order detention in the special institution in any case in which it is satisfied that the mental condition of the offender as shown by the medical evidence and the offence are such as to make him suitable for detention in the special institution, but not such as to justify certification under the Lunacy Acts or Mental Deficiency Acts. The court should have power to call for independent medical advice (which might be from the Prison Medical Service or from other persons) at public expense, and the defence should continue to have the right to call medical evidence. The court should be required to consider a report from the Prison Commissioners as to the suitability of the offender for treatment (as is provided in section 20(7) of the Criminal Justice Act, 1948, in Borstal cases) ; and it should be a requirement that before a special order is made, the Prison Commissioners must have signified to the court their willingness to accept the offender in the institution.

8. A working party should be appointed to prepare notes on the possibilities and limitations of psychiatric treatment, for the guidance of courts in the exercise of the new powers which would be conferred on them.

We think it would be beneficial to find out from certain European countries whether they have institutions similar to that we suggest, and what their law and practice is regarding offenders having abnormal mental characteristics. It would be profitable later if members of the Council could have the opportunity of visiting foreign institutions. The experience of foreign countries might be valuable when it comes to considering the details of the legislation and administration required. If the project is accepted in principle we think the Magistrates' Association should be asked for their observations upon it.

KING EDWARD'S HOSPITAL FUND FOR LONDON

The Duke of **GLOUCESTER** presided at the annual meeting of the general council of King Edward's Hospital Fund for London, held on June 5 at St. James's Palace. He said that the change-over from the traditional patterns to an entirely new and revolutionary system of hospital care had been accomplished smoothly and without serious dislocation of existing services. Indeed, there had already been improvements in some directions, notably in the staffing of hospitals.

> " Such a statement must, of course, be qualified at once. There is the cost of the service as a whole. The Fund has long foreseen a steep increase in cost. It has been conscious that a limit would have to be laid down, and that when that point was reached, a new situation would arise : it would then be necessary to take stock, and decide how the total sum can be handled so as to provide the flexibility needed. This is the situation that confronts the hospitals today. We at the King's Fund see no really satisfactory solution that does not involve a break with the established methods of controlling public moneys. Will the regional boards be given definite round sums on an annual basis which they can pass on to the hospital management committees, and will the hospital management committees be given freedom to deal with these round sums as they think fit ?
>
> " As regards the accountancy of the hospitals, we believe that a departmental system of accounts is overdue, and that it is urgent in everybody's interest that the old system should be replaced by one better adapted to the needs of today. The Minister of Health has on the recommendation of the Central Health Services Council asked the Fund, together with the Nuffield Trust, to conduct a costing investigation in a number of hospitals. This we are glad to do, for we believe that once the advantages of a departmental system are realised the whole scene will be transformed. It will then become possible to allocate money to hospitals rationally, and efficient administration will replace the hit-and-miss methods of today.
>
> " The new situation created by the standstill on expenditure sharpens the problems of hospital administration. There are divergencies of standpoint between the Ministry and the regional boards, between the regional boards and the hospital management committees, between the administrative and financial sides in the hospitals, and between the medical and lay approach to hospital administration. It is obviously important that these friendly differences should not harden into friction, and that the right solutions should be found by discussion rather than the wrong solutions by force of circumstance."

The Fund had embarked on the establishment of a staff college for hospital administrators.

Sir **EDWARD PEACOCK**, the treasurer, in presenting the accounts for 1949, said that the Fund's ordinary income stood at £262,000. Subscriptions and donations, which dropped on the nationalisation of hospitals, had increased slightly, and a number of important institutions which had dropped out in 1949 had renewed their subscriptions. Legacies received during 1949 amounted to over £258,000. In 1949 £150,000 had been received from the Nuffield Trust for the Special Areas. A further instalment of £100,000 received in January this year brought the total so far from this source to £1,250,000. The total receipts for 1949 came to £671,432.

The disbursements during the year were exceptionally large. £250,000 was appropriated for homes for the aged sick, and another £209,860 went in grants to hospitals and convalescent homes. The special services, including various properties purchased, absorbed £77,562. Expenses of administration and of the Emergency Bed Service brought the total outgoings to £573,551. "The Fund is going strong," Sir Edward said, "and in my opinion is perhaps doing the best work in its history."

Sir ERNEST POOLEY, chairman of the management committee, in presenting the draft annual report, referred to the present situation of the hospitals vis-à-vis the principles of control being applied by the Treasury and by the Ministry of Health. In his view the only really satisfactory solution would be to break with traditional methods, the essential thing being that the responsible hospital authorities should know where they stood and should not have to return money saved at the end of the period for which it had been budgeted. This undoubtedly had the effect of encouraging expenditure rather than economy.

The Fund had recently prepared a *Manual for Hospital Visitors*, containing a list of questions for visitors. This was, in his opinion, a remarkably useful piece of work.

As regards homes for the aged sick, there had been a great deal of delay and trouble in finding the right type of buildings and still more in getting permission to adapt them, as well as difficulties about licences and restrictive covenants; but the Fund was going forward and hoped before long to be able to report definite progress. The Fund had been doing a unique work for convalescent homes, never done before, by issuing a compendium of these homes, by real visiting and trying to get their finances in order, and by making grants to bring them up to date. The new directory of convalescent homes was now available.

The division of hospital facilities, which was an important new feature of the Fund's work, was feeling its way. As regards hospital catering, a less ambitious training scheme had had to be accepted than had been proposed, because it was not at present possible to erect a large new building at St. Pancras Hospital. The Fund was going forward by way of modernising the old kitchens, and a grant of £11,000 had been made for this to University College Hospital. The school for medical records officers was going ahead.

ANNUAL REPORT

The Fund's annual report for 1949[1] remarks that there is little or no prospect of a renewed boom in hospital construction, such as continued here for fully half a century until 1939, and is still in full swing in the U.S.A.

> "There is no disposition to despair; on the contrary, it is coming to be accepted that too much emphasis on new buildings and on the latest stainless steel contrivances may easily become a snare and conceal a failure to grapple with the more important things. An old building if judiciously adapted may house better medicine, more gentle nursing and more comfort for the patient; and fortunately many of them, despite their forbidding appearance, embody the Nightingale 'pavilions' which have not yet been decisively out-moded."

The report observes that the success of the nationalised hospital service depends on first-class administration. "Means must be found of reconciling centralised policy and control over expenditure with the maximum freedom in the individual hospitals. This means that it will be necessary to secure a high degree of personal coöperation throughout the administration of the entire Health Service from top to bottom." If the new service is to work smoothly, the objectives, methods, and functions of the different parts of the machine must be understood by all who participate, much as in a modern army undertaking complicated operations. For these ends the methods evolved many years ago by the Local Government Board are largely meaningless; and so too is the institutional outlook, with which the hospital officer of days gone by approached his task. The Fund's hospital administrative staff college will provide: (1) refresher courses for those already holding posts in the hospital service; (2) longer courses for a limited number of younger men drawn, as far as possible, from within the service; (3) a continuous study of the problems and practice of hospital administration, with publication of the results from time to time; and (4) a common meeting ground for all engaged in the service.

One of the Fund's successful new activities is courses for ward sisters, which were started "to provide help and information, to increase the efficiency of ward management, and to encourage those who shrink from its responsibilities." "The ward sister's work does not enjoy the prestige it should as perhaps the most highly skilled of all branches of nursing." The Nursing Recruitment Service has noted "a substantial increase in the number of staffed beds available, and the outlook is bright." At the same time the demand for nurses remains unappeased; and the acceptance, by some of the hospitals which find it easiest to recruit nurses, of responsibility for the chronic sick and the tuberculous is welcomed; "student nurses will undertake these branches of nursing as part of the training offered by their chosen hospital." At first it was the more intelligent candidates who sought information. Now, however, as a result of the spread of general information about nursing, and of better recruitment methods on the part of hospitals, the more intelligent often have a clear idea where they want to train and make their application directly. More and more it is the "difficult cases" which seek advice. "It is much easier," says the report, "to guide a girl from an English public school to a suitable hospital than to find a Matron who will accept a girl from a Turkish household, whom she cannot interview, and whose parents require a number of conditions to be fulfilled before they will allow her to come." Though this type of application requires much detailed work, it often means a recruit saved for nursing; and during the year 147 non-British candidates were accepted for training after consulting the service.

BIRTHDAY HONOURS

THE list of honours published last week contains the names of the following members of the medical profession:

K.C.M.G.

ARTHUR ESPIE PORRITT, C.B.E., M.CH. Oxfd, LL.D., F.R.C.S.
Chairman of the Empire Games Federation; surgeon to H.M. the King; surgeon to St. Mary's Hospital, London.

K.B.E. (Military)

Surgeon Vice-Admiral CLARENCE EDWARD GREESON, C.B., M.D. Aberd., K.H.P.
Medical director-general of the Navy.

Air Marshal PHILIP CLERMONT LIVINGSTON, C.B., O.B.E., A.F.C., B.A. Camb., F.R.C.S., K.H.S., R.A.F.
Director-general, Royal Air Force Medical Service.

K.B.E. (Civil)

NEIL HAMILTON FAIRLEY, C.B.E., M.D., D.SC. Melb., F.R.C.P., F.R.S.
Wellcome professor of tropical medicine in the University of London at the London School of Hygiene and Tropical Medicine.

Knights Bachelor

ALAN NIGEL DRURY, C.B.E., M.D. Camb., F.R.S.
Director, Lister Institute of Preventive Medicine, London.

GEOFFREY JEFFERSON, C.B.E., M.S. Lond., M.CH. Dubl., LL.D. Glasg., F.R.C.P., F.R.C.S., F.R.S.
Professor of neurosurgery, University of Manchester.

---

[1] King Edward's Hospital Fund for London: Fifty-third annual report, 1949. 10, Old Jewry, London, E.C.2.

Wilberforce Stephen Newton, M.D. Melb., F.R.A.C.P.
Physician to the Alfred Hospital, Melbourne; for public services in the State of Victoria.
James Calvert Spence, M.C., M.D., D.SC. Durh., F.R.C.P.
Professor of child health, University of Durham.

C.B. (Military)

Surgeon Rear-Admiral William John Colborne, F.R.C.S., K.H.S.
Major-General Thomas Menzies, O.B.E., M.B. Aberd., K.H.P., late R.A.M.C.

C.B. (Civil)

John Cecil Wilson Methven, M.R.C.S.
Deputy chairman, Prison Commission.
William Rees Thomas, M.D. Lond., F.R.C.P.
Medical senior commissioner, Board of Control.

C.M.G.

William Keverall McIntyre, M.C., M.D. Edin., F.R.C.O.G.
Gynæcologist, Queen Victoria Hospital and Launceston General Hospital, Launceston, Tasmania.
Richard Lionel Spittel, C.B.E., F.R.C.S.
Consulting surgeon, General Hospital, Colombo.
William John Vickers, M.R.C.S.
Director of medical services, Singapore.

C.V.O.

John Douglas McLaggan, M.B., F.R.C.S.
Aurist to H.M. the King and to H.M. Queen Mary; surgeon in charge of the ear, nose, and throat department, Royal Free Hospital, London.

C.B.E. (Military)

Air Commodore Abraham Briscoe, M.B. N.U.I., K.H.P., R.A.F.
Brigadier William Henry Blinman Bull, O.B.E., M.B. N.Z., F.R.C.S.E., K.H.S., R.N.Z.A.M.C.
Colonel Richard Murphy, M.B. Dubl., late R.A.M.C.

C.B.E. (Civil)

Arthur Joseph Amor, M.D. Lond., M.SC. Wales.
Principal medical officer, Imperial Chemical Industries, Ltd.
Hugh McIntyre Birch, M.R.C.S., F.R.A.C.P.
Superintendent of Mental Institutions, State of South Australia.
James Ralston Kennedy Paterson, M.C., M.D. Edin., F.F.R.
Director, Holt Radium Institute, Manchester.
Arthur Bushby Pearson, M.D. Edin., F.R.A.C.P.
Late director of pathology, Christchurch Hospital; examiner in the medical school at Otago University for many years.
Chau Sik-Nin, M.B.
For public services in Hong-Kong.

O.B.E. (Military)

Wing-Commander Lewis McKenzie Crooks, CH.M. Lpool, F.R.C.S., R.A.F.
Lieut.-Colonel John Mackenzie Matheson, M.D. Edin., F.R.C.S.E., R.A.M.C.
Surgeon Commander Ewen Hugh Murchison, M.B. Glasg., R.N.
Surgeon Commander George Desmond Wedd, M.B. Camb., R.N.

O.B.E. (Civil)

Henry Thomas Chapman, L.R.C.P.E.
Member, South Melbourne city council: chairman, Honorary Justices' Association, State of Victoria.
Henry Norman Davies, M.B. Edin.
Specialist medical officer, Tanganyika.
Alderman William Edward Moore Ede, M.D. Camb., J.P.
Chairman, Worcester youth employment committee.
Llewellyn Drysdale Innes Graham, M.B. Belf.
Medical officer, Royal Ulster Constabulary and the Ulster Special Constabulary.
Ludwig Guttmann, M.D. Freiburg, M.R.C.P.
Neurological surgeon in charge of the spinal injuries centre, Ministry of Pensions Hospital, Stoke Mandeville.
Daniel Lamont, M.B. Glasg., F.R.C.S.E.
Surgeon-consultant, Gilbert Bain Memorial Hospital, Lerwick, Shetland.
George Gibson Lyttle, M.B. Lond.
Principal medical officer coördinating civilian medical boards for recruiting, Northern Ireland district.
Patinharam Kunnath Thalathel Krishnan Nayar, M.B.
Medical officer, North Kedah, Federation of Malaya.
William Norman Awdry Paley, M.R.C.S.
For public services in Fiji.
Michael Joseph Petty, M.B. Camb., M.D. Buenos Aires, F.R.C.S.
Senior surgeon, British Hospital, Buenos Aires.

M.B.E. (Military)

Major Sidney Jayawardena.
Ceylon Medical Corps.

M.B.E. (Civil)

Gilbert Rashleigh Hull, M.R.C.S.
Admiralty surgeon and agent, London.
Marthinus Helperus Steyn, M.R.C.S.
Of the medical department, Morgenster mission, Southern Rhodesia.
Luther Reginald Wynter, M.D. Dalhousie.
District medical officer, Antigua, Leeward Islands.

THE NEED FOR REWRITING THE HISTORY OF MEDICINE

PROFESSOR SIGERIST'S ADDRESS

Introducing Prof. Henry E. Sigerist at a meeting on June 7 of the Royal Society of Medicine's section of history of medicine, Dr. Ashworth Underwood, president of the section, recalled that he built up the school at Leipzig before going to Johns Hopkins University as professor of medical history; and that he founded the *Bulletin of the History of Medicine* and edited it until he left America for Switzerland, where he is now engaged in preparing a six-volume history of medicine.

Prof. Sigerist said that he would not have given up his chair at Johns Hopkins had he not felt convinced of the need for the type of book which he was endeavouring to write—a comprehensive history of medicine, fully documented, and written rather differently from previous works on the subject. Until recently medical histories had centred around the physician and what he did, and on Western medicine; they had looked for predecessors and precursors. But the approach of the historian had now been extended, and medical history had to catch up with the other historical disciplines. There were still few centres for research: the institute at Leipzig was founded in 1905 and that at Baltimore in 1909.

When one set about the gigantic task of reconstructing the path of medicine one wanted to know what medicine was like at a given time. This raised the question: what is medicine? The conception of medicine as being the physician and what he did was too limited. Today there was a legal definition of a physician, but who was the physician in antiquity, who the dentist and who the nurse? Anyone could then treat—and charge a fee. Also much illness was treated by the patient himself. This might be according to scientific principles (as a mother repeating for her child what the doctor had prescribed on a similar occasion previously), or it might be conditioned by advertising, or it might be folk medicine. But it should not be left out.

Medical history should cover all the efforts of society to promote health, prevent sickness, treat illness, and rehabilitate the sick, so that it included not only the physician but statesmen and others.

One had to start by making a study of the health of the community at a given time. The incidence of disease was determined by geographic and economic considerations, and therefore one must begin with an analysis of the geography of the country. In Egypt, for instance, the flooding of a river determined the social organisation and the events in the land. It required social organisation

—that north and south should coöperate—and determined the pathology of disease. People of common race went to India and Greece, but in India they became vegetarians, whereas in Greece they remained beef-eaters. In Greece communities living in small valleys did not need to coöperate as in Egypt. The medical historian wanted to know how people lived—how they worked and how they rested. He wanted to know what they did to maintain and promote health—and all people did something to this end, consciously or unconsciously. Education was of importance. The historian needed to know also what was done in public health. Public health required State control; it must therefore be approached from two angles. First there was the medical. (But knowledge was not enough—we might know how to wipe out venereal disease and tuberculosis, yet we still had them for a number of reasons.) Secondly there were non-medical, non-scientific reasons which had to be understood. And the medical historian wanted to know what happened when health broke down.

There were two sources for the physician's action; one was experience, the other theory. Definite views on the origin of disease affected the approach to its cure; when, for instance, it was regarded as the punishment for sin, one tried to placate the deity: if it was regarded as a disturbance of the balance of the humours, one tried to restore the balance. Theories were also determined by experience. The Egyptians had their theory of *mitu*, for example, the canal theory of ætiology; Egypt had a system of canals and they knew what it meant when these were obstructed. Every theory, Prof. Sigerist pointed out, was correct once, until it was superseded by another. The medical historian must place himself in the position of a naïve observer. Concepts available at a certain time were limited, and if a person was far ahead of those concepts he had no influence—certain Alexandriates, for instance, had an idea of the anatomical concept of disease. If one saw theories as the product of their times, they no longer appeared fantastic.

Turning to the medical historicobiographical approach, Prof. Sigerist said that, in the event, medicine was made by individuals, and there had always been great doctors. History made a certain selection of who were great doctors. One found that many doctors who had been painted by famous artists were forgotten today: others were remembered as great scientists; some as great doctors. Among the latter Prof. Sigerist classed Sydenham, Boerhaave, and Osler, because they came nearest to the medical ideal of their time. Every age had its medical ideal, and the object of doctors' training was to bring them as close as possible to that ideal. The time and place at which a man lived also determined to what extent and how his genius developed.

Medical discoveries were usually not the work of one man alone, and Prof. Sigerist objected to the search for "fathers"—the father of surgery and so on. It was not fair to the mother and the midwife and the obstetrician. Harvey was one of the greatest medical scientists, but he had precursors. One had also to study how quickly great developments benefited the ordinary patient. It was equally important that one should have a high standard of general practitioners to apply the discovery of the great doctor. So the medical historian had to study the rank-and-file doctor and the other medical workers.

Medicine was not a pure science—it was a social science. There were always two groups involved—the medical workers in the broadest sense, and the public. The historian ought therefore to study the social environment, and consider the attitude which society took towards disease and the position which it gave to the physician. He should study the measures which society adopted to protect itself against abuse of the physician's power by codes of ethics and legislation.

The historian had to apply general methods of research to create a picture of the past. When he had done this, he had to communicate his knowledge, and this was why so much depended on the personality of the historian. The historian was the memory of society, and his work was related in many ways to that of the philosopher, who was its intellect. As a rule the medical historian was a physician who kept in touch with medical developments and who looked at medicine as a whole, not merely from the viewpoint of the physician but also from that of society.

Of the value of medical history, Prof. Sigerist remarked that he knew that without historical knowledge he would have found his practical work in public health much more difficult. History was the compass guiding to the future. In America he had been in the midst of the controversy over socialised medicine. One did not talk of "socialised" education or a "socialised" post-office, but medicine was called "socialised" apparently to scare people. He found that many were opposed to the development because they did not know the history of medicine.

The historian had a great responsibility. The biographer re-created the man—for instance, to younger men Osler was the man Harvey Cushing re-created in his book. History had its fakes like everything else, and the pseudohistorian was a menace. The medical historian must endeavour to approach his subject objectively. One who did not was like the scientist who faked his laboratory reports.

Prof. JOSEPH NEEDHAM, F.R.S., proposing a vote of thanks to Professor Sigerist, said that the importance of the social concept in approaching the history of medicine applied to the whole of the history of science. Prof. BENJAMIN FARRINGTON, seconding, said that Professor Sigerist had turned history outwards. He thought that at the present time there was too much intellectualism.

THE FOUNTAIN

IN 1893, to cope with an epidemic, an emergency fever hospital of 384 beds was built in Tooting. The sixteen wards were temporary structures of wood and corrugated iron, run up hastily for a transient need. They are still there after 57 years—all except three, which were destroyed by a flying bomb in 1944. The beds, however, are now closer together, and the occupants are no longer fever patients but mentally defective children. At the peak of overcrowding, during the war, the sixteen wards held 890 beds; and though the numbers are now down to 680, the loss of three wards means that overcrowding has not been greatly reduced.

This is the only mental-deficiency hospital in the National Health Service which caters specially for the care of children of all ages between a few weeks and sixteen years. The haphazard origin of its buildings has meant that it laboured under great difficulties; but it has always done good work, even when the old-fashioned view prevailed that there was nothing to be done with mental defectives except to look after them. It has always had a good school inside the hospital, and has been fortunate in attracting and keeping many kind and capable nurses whose life and interests came to be bound up with those of the children. In the last few years, however, Dr. L. T. Hilliard, the physician-superintendent, has been able to use a strong gift for improvisation to develop the unpromising buildings and to improve the prospects of both patients and staff; and this, he thinks, has been made possible by the flexibility of the National Health Service Act.

WIDER OPPORTUNITIES

The hospital comes under the South-West Metropolitan Regional Hospital Board, and is nowadays the chief of a group of three institutions. The Ellen Terry Home at Reigate is reserved for mentally defective children who are also blind. The South Side Home, on Streatham Common, is a hostel for the adult mentally defective workers who used to occupy a ward in the Fountain. They now live out, and travel to and from their work in the hospital's private motor-coach. Their hostel life is made as natural and unrestricted as possible: after years of life behind locked gates they are now allowed to go out shopping or to the cinema by themselves; and in these and other ways they are unobtrusively prepared for the chance of going out on licence. As Dr. Hilliard put it at the first annual meeting of the Fountain Group Hospital Management Committee, on May 24, "You don't learn to live in the community by being locked up in an institution." About three-quarters of all defectives, he added, are in the upper grades, and most of these can be fitted for life in the community.

The Fountain accepts children of the lowest grades, many of whom will always need care; but even among those who look hopelessly defective in the early months or years some will prove to be educable and will ultimately be able to live an ordinary life; and nowadays a fairly high proportion of the adult workers go out on licence—or even come off licence altogether. Of the 60 adults who have been away from the Fountain on licence for over two years, over half have been discharged from care under the Mental Deficiency Act.

The hospital school, or occupations centre, takes about 200 children, and nowadays accepts about 16 children living with their own families in the neighbourhood who have no local occupation centre within reach. The brighter children from the hospital attend a special school, held daily in the South Side hostel, travelling to and fro in the coach.

THE PARENTS

An energetic hospital management committee, under the chairmanship of Mrs. Eileen R. Hoare, has fostered many developments on the social side. Parents are now encouraged to take a close interest in the life of the hospital, to visit their children often, to take them out, on visiting days, for walks and bus rides or for tea without having to make an application in advance, and to have them home on leave for short periods. On alternate Sundays the coach takes parties of parents and children up to Epsom Downs. The parents have now formed themselves into a group—the Friends of the Fountain—and are taking a warm interest in the children's welfare. They contributed to the purchase of the famous coach, in which the children take a strong proprietary interest, and they are helping to equip, with swings and a sandpit, the playground which has been laid down on the site of the bombed wards. One part of the playground has been railed off for the use, by the children, of tricycles presented by the parents. This hospital was not evacuated during the war: the old shelters make very good tricycle-stores. There is also a hospital zoo, with a goat, some chickens, ducks, guinea-pigs, and a rabbit—a very popular corner of the grounds.

THE STAFF

The nurses' quarters were never greatly to the hospital's credit in the old days: dark dingy little rooms, ill furnished, were as much as the Fountain had to offer. Structurally the rooms are the same, but the paint is clean and light and the furniture new. The nurses' common-room, too, has been repainted and has a good wireless set. Trained staff can live out if they wish, and in any case they no longer occupy rooms on the wards as they used to do. The students now go into a preliminary training school for eight weeks on joining, and have a well-equipped lecture-room with an epidiascope, and an invalid-cookery room where some cookery really gets taught. All the nursing staff work a 96-hour fortnight.

Staff and patients alike have the benefit of the physiotherapy department when they need it, and lately a visiting chiropodist has been appointed to look after the feet of both patients and staff. A hairdresser now cuts the patients' hair—a duty which used to take up quite a lot of the nurses' time.

SPECIAL TREATMENT, TEACHING, AND RESEARCH

Many of the cases at the Fountain are of great medical interest. A neuropsychiatrist has joined the staff and will undertake specialised research. A visiting orthopædic surgeon has attended for many years to correct or relieve the disabilities of suitable patients, and the dental surgeon attends for two sessions weekly. An ear, nose, and throat surgeon, an ophthalmologist, and a neurologist also pay regular visits. More than 60 lectures and demonstrations on mental deficiency were given at the hospital to visiting classes last year. A social worker, lately added to the staff, will help with the visiting of patients on leave or licence.

To those who knew the hospital in the past and recognise the importance of its structural drawbacks, the advances made in the last few years are exceedingly impressive. They show what can be done by the use of good wits and a liberal spirit, even in the most adverse conditions. Moreover, the idea that all mentally defective people must of necessity be a dead weight on the community is thoroughly exploded at this lively place.

MEDICAL SUPERINTENDENTS

At the annual meeting of the Medical Superintendents' Society, in Newcastle upon Tyne on June 7–9, Dr. J. R. Murray, the retiring president, gave a spirited defence of medical administration of hospitals. Dr. Murray observed that the society would be called on to give evidence to a committee set up by the Central Health Services Council to examine the internal administration of hospitals; and he went on to suggest some fields in which the medical administrator could not, in his view, be suitably replaced by a layman. Among these was the admission and discharge of patients, and the allocation of beds: "it is quite as important for the well-being of the service that beds should be used intelligently and to the best advantage as that they should be occupied." As regards economy in drugs and other items, "circulars descending from the Ministry prompt hospital secretaries to an ill-informed and irritating concern about these matters"; whereas a medical administrator was better placed to discuss technical details and to maintain elasticity, while generating restraint and a corporate desire for economy with efficiency. Among the further duties which a medical administrator was better equipped to perform were the following: dealing with complaints by patients or inquiries by relatives; the building up of a satisfactory relationship with local practitioners; the solution of epidemiological problems; a decision on whether a death should be reported to the coroner; help in setting up new departments and integrating these with other departments; liaison with the matron; supervision of medical staff; advice on research projects; and protection of the staff's health. Dr. Murray declared: "We have allowed medical administration to be put upon the defensive. Instead of pointing out the manifest failures of lay administration . . . we have allowed ourselves to be hypnotised by the cobra-like gaze of the predatory laymen."

In England Now

A Running Commentary by Peripatetic Correspondents

Two Danish visitors, asked what had impressed them about England, replied simultaneously: "Your dirty food!" After that they went on to mention St. Paul's and the Abbey. We are supposed to be having a campaign for clean food just now; and it is generally agreed that one way of making it safer would be to get the nation to form the habit of washing the hands after using the toilet. With a little encouragement, we say, it should not be so difficult. With a little encouragement. Last week, accompanied by a friend, I visited the public lavatory in Leicester Square, and being a woman was required to pay 1*d.* before I could even get inside the place. When I came out of the toilet, I asked to wash my hands and was required to pay 3*d.* for the use of the towel. My friend also wanted to wash her hands, and I naturally said: "Share my towel." But the poor woman in charge shamefacedly explained that she was obliged to extract yet another 3*d.* and provide yet another towel. Hygiene at 8*d.* for two people comes expensive. I know that the public lavatories have to be maintained, but I suspect that the tariff falls unfairly. Men, I am told, are not always charged even 1*d.*; and most of them don't bother to wash. It looks to me as though the women pay for both. Quite apart from that, who cares to learn good habits and be fined for them?

* * *

Our dermatological club paid a four-day visit to Belgium a few weeks back. Some of us went by car and some by plane, and each arrived in Brussels pleased with their choice. The car-drivers had spent happy hours in Bruges la Morte or at the superb flower show which was being held in Ghent. Belgium is a great azalea-exporting country and there were huge banks of these lovely flowers in every shade. I chose the air passage and found it full of interest. The dreary London suburbs are soon exchanged for the tracery of water and sand, and flat green strips of the Thames estuary; strange desolate country, so little altered by civilisation that one half expected to see a Roman galley or a Jutish long-boat come round the next bend. Then a brief skim over the North Sea and below lies tidy Belgium, a flat chequer-board of rectangular fields. It seemed impossible that there could be so many variations in the green and brown of earth and growing crops. Here and there one saw a big country house, rather pompous and castellated in its formal garden, jutting out into a little moat of a lake. This building tradition, I believe, goes back through the centures to a prehistoric civilisation of lake dwellers, just as the great central archway of the Vosges farms derives from the ancestral caves.

We all forgathered at Brussels on a Saturday night. Life is comfortable there but very expensive by English standards. Morning coffee and roll, for example, costs 4*s.* Two or three of our more adventurous members went to a night-club with a floor show, and found that the only tipple was champagne at £8 a bottle. They assured us defensively that "The Cow on the Tiles" was well worth it.

On Sunday morning at 10 o'clock we started work with a visit to the University Hospital in the Rue Haute, where Professor Craps and his colleagues had collected an excellent show of cases and moulages, after which we made the acquaintance of our hosts at luncheon in the Institut Jules Bordet. This was followed by a meeting of the Belgian Dermatological Society. Sunday sessions are the rule there and our hosts remarked that only in England was life so leisured that weekday work could be interrupted by meetings. Fortunately the excellent dinner to which we were bidden that evening was also quite un-English. On the Monday we drove to Namur for a visit to the Military Hospital, where Dr. Dupont gave us an illuminating demonstration on the histopathology of the skin. No sooner was this over than he whisked us off to his own house, where his hospitable wife and children served us all with lunch—no mean feat with 20 hungry foreign guests. Next day was spent at the Hôpital Bavière at Liege. This is a big industrial centre with plenty of clinical material, and Professor Lapière has a fine department. Its lighting and general arrangements made us very envious, the more so as w were assured that it was to be replaced by somethin better in four years' time. More wonderful hospitality this time at the Restaurant Vieille France, whos panelled walls and perfect cuisine fully justified its name

Our last day was spent in Antwerp under the guidanc of Dr. Eyckmans at the Hôpital Ste. Elizabeth. This i a 13th-century foundation and still uses one of the ancien wards, an immensely high hall supported on a centr row of stone arches, and lit on both sides by tall windows. High up on one wall is a recess with an altar so that the sick, like Browning's Bishop, may "lie . . . and hear the blessed mutter of the Mass." The hospital is served by Augustinian nuns, whose white corded coifs look like Dürer etchings. How was it that the simple folk of those days had such an art in their fingers that when they folded a piece of linen round their heads it took on this sculptural perfection? Today we must go half-way round the world, to Bali and its sister islands, to find this same instinctive skill. The great ward breathed the tranquillity of another age and mode of thought. One felt one could be half in love with easeful death in that sunlit quiet, looked after by the white coifed sisters with their serene faces and the beauty that, as in Rembrandt's old women, comes from the heart and not the epidermis. "It is a beauty wrought out from within upon the flesh, the deposit, little cell by cell, of strange thoughts." The good sisters had not trafficked for strange webs with Eastern merchants nor been divers in deep seas, so their deposit is different from the Mona Lisa's! But what an intriguing subject for research, combining the psychosomatic, the microscopical, and the clinical approach. Perhaps in 50 years examination candidates will be asked: "Trace the development of Pater's cells in a nun, a woman minister, and a cabaret artist."

But at this point my fancies were interrupted by one more splendid lunch, with succulent steaks specially chosen by our host for his English guests. And so home again, full of memories, new friendships, and lasting gratitude for the warm welcome and boundless hospitality of our Belgian hosts.

* * *

Carrying my bag I brisked out of the station. The railway constable, as I passed him, put his hand to the peak of his helmet and made a curious sign, but I attached no importance to it. Presently I was tapped on the shoulder and turned to see a nondescript-looking fellow, in plain clothes and hatless, who assured me that he was a policeman and produced a document to prove it. I wondered how I might be of service to him. "Is that your bag?" he asked. "Of course," I replied, and scrutinised it hastily and closely to reassure myself. "Will you please tell me what it contains?" "So far as I remember," I replied, thinking aloud, "nothing except my night attire, shaving tackle, a couple of books, some sweets, and a spare pair of trousers." "Will you give me your name and address, please?" I gave them. "Now will you open the bag?" "Open it yourself," I said, "it isn't locked." He did so, found everything in order and apologised. He even called me sir. "You see, I've picked up two already this morning walking off with somebody else's property." We parted on the best of terms. But what I want to know is why, when one is absolutely innocent, one always feels so guilty when questioned by the police.

Rural Tap-water Stops Development of Tadpoles. Doctor Finds Possible Clue to Health Troubles of Local Population—see I.E.N. for June 3 (p. 1049). Ye gods and little fishes—guppies, to be precise. The third generation was coming along nicely in a tank in my surgery in London when a refill with fresh tap-water produced a sudden and comprehensive mortality. Previous replenishments (same tap, same amount) had only increased their joie-de-vivre. Ought I to tell the M.O.H. at once (*Doctor's Fish Save People of London*)?

* * *

A youngster, just admitted to the sanatorium, was being questioned about his family contacts. "Has your sister been to the Chest Clinic?" I asked. "Oh, yes, doctor," came the reply, "and they're going to give her those N.B.G. injections."

Letters to the Editor

ARTANE IN THE TREATMENT OF PARKINSONISM

SIR,—We have read with interest the paper by Dr. Ellenbogen in your issue of June 3; and we agree in the main with his conclusion that 'Artane' is "a powerful remedy possessing the advantages of belladonna alkaloids without their disadvantages."

We have in this hospital about 200 cases of post-encephalitic parkinsonism, the majority of which in the past have been treated with large doses of stramonium (up to 30 minims of the liquid extract, or its equivalent, t.i.d.). We were firmly convinced of the superiority of this form of therapy over any of the other standard treatments.

We have found no satisfactory objective test of the value of any drug in the treatment of parkinsonism: the rigidity, tremor, and oculogyric crises are grossly modified by variations in emotional tone and by suggestion. We have been compelled, therefore, to rely on an appreciation of the patients' over-all performance over a period of time, and not on clinical tests. We feel that the favourable results with artane in our group of patients are unlikely to be due to suggestion because, through the years, both patients and nursing staff have so frequently observed the failure of new remedies that they have become highly critical of any change in treatment.

In order to assess the value of artane, as of other drugs, we have first of all stopped administration of stramonium, either abruptly or gradually. This sometimes produces quite severe withdrawal symptoms, and patients have hitherto demanded vigorously that their stramonium be returned to them. When artane has been given, withdrawal symptoms have subsided rapidly and the patients have soon reported a feeling of well-being.

Altogether 35 patients have been under treatment with artane for periods varying between one and three months. Of this number, only 7 have failed to improve, and none has deteriorated. No side-effects have been noted except in 2 patients. who showed some temporary mild excitement whilst having 10 mg. thrice daily. In our experience the recommended dose is inadequate, at least in the more severe cases. We have found it expedient to start treatment with a dose of 5 mg. thrice daily, and to increase the dose gradually as long as the patient shows clinical improvement. Several cases have received 45 mg. daily, but there has been no evidence of improvement with doses in excess of this. The absence of side-effects with this large dosage is noteworthy.

The type of improvement noted by us was a well-marked decrease in the emotional hebetude so characteristic of the disease; the patients became more active and there was an increase in the play of facial expression. Rigidity and tremor were decreased, and patients found themselves able to use their hands and to walk much more easily. One patient's relatives stated that they had received their first letter from her for five years. We have observed no changes in the frequency or severity of oculogyric crises. We found (much to the patients' comfort) that the mydriatic effect of artane was much less than that of the solanaceous drugs, even in the large doses we have used. Sialorrhœa is less well controlled by artane than by atropine.

Completion of our observations has been held up by a failure in the supply of artane. At this stage we feel that only its prohibitive cost is likely to prevent it becoming the drug of choice in the treatment of post-encephalitic parkinsonism.

Our thanks are due to Dr. G. A. Borthwick, medical superintendent and director of the unit, for affording us facilities in this investigation.

MULTIPLE-LEAD ELECTROCARDIOGRAMS

SIR,—I enjoyed reading the comprehensive article by Dr. Hill which appeared in your issues of May 27 and June 3.

There is one point I should like to mention regarding the diagnosis of bundle-branch block by means of the electrocardiogram. Dr. Hill rightly emphasises the importance of the precordial leads in differentiating the various types of bundle-branch block. However, it has been stated that there is a very useful rule for differentiating right from left bundle-branch block—namely, that the presence of an S wave in lead I of the standard limb leads, in the presence of wide QRS complexes, denotes that the block is of the right branch. With left bundle-branch block there will be no S wave in lead I. Though this fact does not in any way detract from the value of the precordial leads, I think it does enhance the usefulness of the standard limb leads and therefore will substantiate the diagnosis. I noticed that in all the illustrations of bundle-branch block in Dr. Hill's article this rule seems to apply. This includes the illustrations of the Wilson type of right branch block and a rare type (figs. 18a and 18b).

I should like to know whether this rule is still regarded as reliable and useful, or whether it has fallen into disrepute.

London, S.E.5.

CYRIL JOSEPHS.

SUBSTITUTES FOR CURARE

SIR,—Your leading article of June 3 is, unfortunately, a true reflection of the opinion of most anæsthetists in this country. In comparing the relative merits of various synthetic relaxant drugs, the usual undue emphasis has been placed on matters which would bear further consideration. There is some reason to think that mephenesin, as commercially obtainable, does produce intravascular hæmolysis. The same is perhaps true for many drugs which are given intravenously.

It has already been shown[1] that the evidence for hæmoglobinuria is decidedly less; since breakdown products of the drug may produce a positive reaction to the benzidine and guaiac tests, the proof of hæmoglobinuria seems to be lacking. In any event, there is little sign of any adverse effect on the patient. In this institution. mephenesin is used routinely by several anæsthetists to produce relaxation in infants and small children during abdominal operations. This has been my unbroken practice for three years, and the results justify the technique. We have already reported the successful use of mephenesin in the treatment of tetanus,[1 2] and further experience not only confirms the early impression but also shows that, despite large dosage of mephenesin continued for several days, it has no obvious adverse effect upon the organism.

It must be admitted that the relative values of 'Flaxedil' and decamethonium iodide are not yet assessed. Both these drugs have been widely employed to a considerable extent in this hospital; and at present the latter is preferred. With decamethonim iodide, it does seem that the duration of respiratory depression is shorter than that of abdominal relaxation, and that the total duration of action is shorter than that of flaxedil. It is quite true that one occasionally sees a fall in blood-pressure with this drug, but this responds immediately to the administration of ephedrine or 'Methedrine' intravenously. This disadvantage is offset by the rise in pulse-rate which so frequently

2. Davison, M. H. A., et al. *Brit. med. J.* 1949, i, 616.

accompanies the administration of flaxedil, and which may be a source of embarrassment should other adverse influences be in operation at the same time.

Concerning both mephenesin and decamethonium iodide, your leading article emphasises the absence of any reliable antidote. The action of mephenesin is such that no antidote is required; and the duration of respiratory depression with decamethonium iodide is so short that artificial respiration for more than 10 minutes is required only exceptionally. Thus, that antidotes are unnecessary is a strong point in favour of both these drugs.

SURGICAL TREATMENT OF CARDIAC ISCHÆMIA

SIR,—Little has been published in this country on the surgical treatment of cardiac ischæmia since O'Shaughnessy[1] described the operation of cardio-omentopexy. In America, however, there has been a steady stream of articles on the subject. No doubt much of the scepticism that is apparent here can be attributed to the difficulty of assessing the value of any surgical procedures in a condition whose course is notoriously unpredictable.

Recently four cases of cardiac ischæmia have been referred for surgical treatment by Dr. W. A. Bourne. All presented abnormal electrocardiographs and were suffering pronounced chest pain; and all other methods had failed to relieve them. The surgical treatment consisted of the insufflation of talc into the pericardial sac, with the intention of producing an increased blood-supply to the ischæmic myocardium.

The coronary arteries are end-arteries, so that the occlusion of their lumen produces either an area of ischæmia or an infarct. Local ischæmia leads to local anoxæmia, and the area may become a "trigger" for ventricular fibrillation. But if an adequate collateral circulation can be established the irritability of the anoxic zone may be diminished and the viability of the myocardium preserved, thus preventing it from degenerating into scar tissue.

With cardiac ischæmia intercoronary communications may develop spontaneously. Harrison and Wood[2] have described the changes found post mortem in the coronary tree of ischæmic hearts.

> Severe narrowing or occlusion—usually both—was constantly present. In 8 of the 15 hearts examined, the whole coronary tree was affected; while in the other 7, arterial narrowing was limited to either one vessel (usually on the left) or to part of one vessel. Infarction was found in 13 cases. Anastomotic vessels, just large enough to be visible after injection of the coronary tree and radiography, were noted in all cases; these were related to the distal parts of the occluded vessels and sufficed to permit retrograde filling of these vessels.

Beck[3] has shown experimentally that a heart that can tolerate obliteration of a coronary artery will, in the course of a few weeks, establish good communications between the coronary arteries. He emphasises that the important question is whether the patient can live long enough for such communications to develop.

The surgical approach to the problem of increasing the blood-supply to the ischæmic myocardium has developed along two main lines: the production of extracoronary communications, and the establishment of intercoronary anastomoses. As regards the first of these, grafting of tissues to the surface of the heart will produce arterial connections with the coronary tree. Many tissues have been used for this purpose—notably lung, mediastinal fat, omentum, stomach, and spleen. This method was adopted by O'Shaughnessy[4] in evolving the operation of cardio-omentopexy. Other workers, in America, have also pursued this line; but, while arterial communications have invariably been produced, doubt has arisen as to the adequacy of the anastomotic channels; as Burchell[5] says: "the possibility that the small vascular connections between a graft and the heart might develop to a functioning value cannot be denied but, in the experiments seemingly favourable to such a result, it has not occurred."

Aiming at a more widespread blood-bath to the myocardium, Beck[3] conceived the idea that the production of a bed of granulations on the heart surface would increase vascularity and distribute blood to every part of the heart. At first he used powdered beef-bone as an inflammatory agent. Later, in experimental work, he exposed the heart and abraded the epicardium with special burrs; three weeks later he again exposed the heart and ligated the descending ramus of the left coronary artery at its origin. Subsequently intercoronary anastomoses could be demonstrated, and in some cases infarcts were small or even absent.

In man the use of burrs is unnecessary; the inflammatory reaction can easily be evoked by other agents. The choice of agent is important, for it must not cause too severe a reaction nor must it lead to constrictive pericarditis. Schildt, Stanton, and Beck[6] found that croton oil, santal oil, formaldehyde, and acriflavine were strong irritants; sodium morrhuate and sodium ricinoleate produced a temporary reaction which disappeared in a few weeks; silica, sand, agar, cotton, and typhoid vaccine were not suitable. Asbestos (calcium and magnesium silicate) was regarded as the best of the substances investigated. These workers did not support the claims made by Thompson[7] for talc, nor those by Heinbecker and Barton[8] for lionite, aleuronat, and starch.

More recently Thompson[7] has again advocated the use of talc (hydrous magnesium silicate), because of its capacity to produce a well-marked foreign-body reaction. In the pericardial sac talc gives rise to hyperæmia of the myocardium, epicardium, and pericardium and results in an adhesive pericarditis. In the dog talc granulomas are characterised by a loose fibrous-tissue lesion, but in man the tissues react by forming pseudotubercles.[9] Thompson concludes from experimental work and clinical observation over nine years that the adhesive pericarditis produced by this method is not constrictive and does not limit its usefulness nor add any extra burden to the heart.

The operation of pericardial insufflation is simple and can be performed without shock to the patient.

> General anæsthesia is best, since it avoids the risk of an anginal attack during the operation. Each of the four patients mentioned below was given bromethol (0·08 g. per kg. body-weight) three-quarters of an hour before operation, and nitrous oxide, oxygen, and ether uring the operation; care was taken to ensure full oxygenation throughout.
>
> In these four cases the approach has been, not by division and removal of portions of rib or cartilage, but by an incision some 3 in. long along the lower border of the left costal margin. After opening the rectus sheath the muscle is retracted outwards and the loose plane of cleavage entered in an upward direction until the pericardial sac is reached. A small transverse incision is then made into the sac. All excess pericardial fluid is aspirated and, by means of an insufflator, 2 drachms of talc is introduced. The talc can be placed anywhere desired if a soft rubber tube is attached to the nozzle of the insufflator; this can be passed up behind the heart and well over the right border. In no case has any attempt been

made to inspect the surface of the heart for visible evidence of ischæmia or infarction, nor has the heart been palpated; and thus it has not been found necessary to introduce any local-anæsthetic solution into the sac during operation. The wound is closed without drainage.

In this brief communication no attempt is made to discuss the selection of cases for surgical treatment or to assess results. The four patients treated (three of them about a year ago) are quite convinced that the operation has definitely relieved their symptoms; but since no case has come to autopsy there is no direct evidence that an increased blood-supply has, in fact, been produced. Nevertheless, all four cases have been improved according to the criteria laid down by Thompson [7]—relief of anginal pain, increase in exercise tolerance, relief of incapacity, and increased ability to travel and deal with daily needs.

ESTIMATION OF PROTHROMBIN-TIME

SIR,—We have observed in this laboratory that irregular results in measuring the prothrombin-time, using thromboplastin ('Difco'), were due to the fact that we had used soapless detergents for cleaning our glassware. Even if all laboratory glassware is cleaned by chemical means, results will still be irregular if the containers in which the blood is collected have been treated with such soapless detergents. It seems that this effect is not generally known, and I would like therefore to bring it to the notice of other laboratory workers.

Pathological Laboratory,

PROPHYLACTIC NEOSTIGMINE IN ELECTROCONVULSIVE TREATMENT

SIR,—In his letter of June 3, Dr. Silfverskiöld outlines his technique for using neostigmine as a prophylactic against curare depression of respiration following electroconvulsive therapy (E.C.T.). I see no advantage in the method he described over that which I have often used to offset the depressant effects of curare with a prophylactic dose of neostigmine.

It has been my practice to administer by rapid intravenous injection *d*-tubocurarine (2 mg. per stone body-weight, unless a small test dose shows excessive sensitivity), gr. 1/100 of atropine sulphate having been given subcutaneously 45 minutes before.

The syringe is then detached from the needle, which is left in the vein, and replaced by one containing thiopentone-sodium solution, altogether 0·2–0·3 g. being given slowly during the interval (usually 4–5 minutes) between the injection of the curare and the production of its full effects. At the appropriate time the thiopentone syringe is detached from the needle and replaced by one containing 1 mg. of neostigmine, which is immediately injected, the syringe withdrawn, and the electro-shock given without delay.

The method is based on the same principle as that underlying Dr. Silfverskiöld's technique—namely, the appreciable latent period before injected neostigmine exerts its anti-curare action. The modified convulsion has ceased before the neostigmine neutralises the curare. It is suggested that curare should always be followed by a thiopentone-sodium injection, since the effects of the former are rather terrifying in a conscious patient.

Recently, I have been less happy about the *routine* use of neostigmine before E.C.T., having several times noticed a rather pronounced slowing and weakening of the pulse after intravenous neostigmine. It seems possible that a vagotonic patient might suffer undue depression of the heart at a time when this organ is under great stress following a series of convulsions. However, Dr. Silfverskiöld appears to have had very little trouble with his 80 cases.

Park Prewett Hospital,
Basingstoke.

J. TODD.

ORIGIN OF PLACENTAL TROPHOBLAST

SIR,—I welcome Professor Mossman's letter of May 20 and the philippic by Prof. Emil Novak elsewhere,[1] as I find with relief that two such eminent leaders of the profession cannot produce anything more decisive than they have done. In fact neither of these criticisms disproves my hypothesis, any more than my own paper proves it.

I will deal with Professor Mossman's criticisms in turn.

1. It is granted that œstrogens and gonadotrophins are obtainable from a wide variety of sources. My argument, however, is that both follicle cells and trophoblast produce œstrogens, progesterone, and androgens. Why gonadotrophins have been introduced in this context I am unaware, as they are not produced by follicle cells, and my argument is that they are not produced by the trophoblast either.

2. The reason why trophoblast should not survive independently of the embryo if it were of fœtal origin is that it is unusual in nature for a part of an organism to continue to live for a material length of time when the organism itself has died. (Normal trophoblast is not a tumour.)

3. The origin of chorionepithelioma, as of most other tumours, is unknown, and I do not attempt to explain it. It is more rational, however, to believe that it occurs as a result of a change in cells of the individual himself—i.e., follicular cells, or their analogue in the male—than of a malignant change of cells belonging to an individual of another generation in the host.

4. The assumption that the ovarian reaction in mole and chorionepithelioma is evidence of secretion of gonadotrophins by the tumour is just as speculative as my theory that both are evidence of the action of the hormone; especially as Mossman explicitly states that the hormone cannot be extracted from the tumour.

5. Endometrial stroma does not form a new growth under the influence of gonadotrophin as granulosa cells apparently do. The analogy is thus inapt.

6. With reference to Ericulus, it is not essential to my argument that the follicle should have cavities or the ovum a corona radiata. All that is required is that follicle cells should be available when the blastocyst embeds in the endometrium, however they may have arrived there.

7. The fact that follicle cells and trophoblast have analogous functions is of course no more than suggestive that possibly they have the same origin. The introduction of mammary epithelium in a similar context is of course innocuous rhetoric.

8. The substance of this complaint is apparently that one must not venture new concepts as it will confuse students.

9. All stages of transition can be seen between the different cells of the epidermis.

10 & 11. I do not wish to labour the points of similarity in culture, nor the placenta of the hyracoidea. They are merely incidental illustrations of my main thesis.

12. Professor Mossman has evidently completely misunderstood my argument with respect to transplantation of tissue. The trophoblast is in a completely different relationship vis-à-vis the maternal tissues than the fœtal mesoderm is, for the trophoblast has a maternal circulation and the mesoderm a fœtal one. It is vascularisation by the host that causes the death of a transplant, as Medawar and others have shown.

The remaining arguments are merely statements as to how obvious it is that the prevalent conception is right, without giving specific instances. The fœtal origin of trophoblast may indeed be true, but if it is wrong it is because of misinterpretation of what I call the "isolated frame"—i.e., the histological section. A frame is one picture from a reel of film. The section is an "isolated frame" because the pictures preceding it and after it can never be obtained as the organism must be killed in the act of obtaining it. Thus the interpretation of processes must always be a matter of inference and not observation. Tissue culture under continuous observation does not suffer from these defects; but tissue culture supports me rather than Professor Mossman, as it is well known that both granulosa cells and trophoblast spread and grow luxuriantly in culture, yet the blastocyst, from whose outer wall the trophoblast is said to arise, always remains in culture a regular ordained sphere.

---

[1] Obstet. Gynec. Survey, 1949, 4, 828.

I trust, Sir, that there will be no further correspondence on this subject, as it is a matter to be settled by experiment rather than by polemics. Over the last eighteen years I have grown accustomed to jibes of being an "armchair" scientist in this regard, and asked to produce evidence of my experiments. A vicious circle has arisen in that first opportunity to experiment has not been given by sceptical professors; then when the idea is published, rather than that it should die with me, I am blamed because there are no experiments. May I suggest to Professor Mossman, or any others sufficiently interested and lucky enough to have the opportunity, that the problem of the origin of the trophoblast might be settled in this way. Fawcett et al.[2] have developed the technique of transplanting mouse ova to the anterior chamber of the eye, where trophoblast grows luxuriantly. It should not be difficult to transplant each tissue concerned separately, and in various combinations, to decide which gives rise to trophoblast—i.e., granulosa cells alone, unfertilised ova with attached corona radiata, fertilised ova with all granulosa cells removed beyond all shadow of doubt (by hyaluronidase), and, if necessary, fertilised denuded ova to which granulosa cells have been added.

I regret to have wasted so much of Professor Mossman's time, of which he complains. I am aware of his erudition in this matter, and of my ignorance; but study of the progress of science in the past has often demonstrated that a lot of learning may be a dangerous thing.

ISRAEL GORDON
Acting Medical Officer of Health.

Ilford.

T.E.A.B. IN RHEUMATOID ARTHRITIS

SIR,—In your issue of June 3, Dr. Fløystrup appears to judge the efficacy of tetraethylammonium bromide (T.E.A.B.) by temperature changes. In the cases quoted by him, there is no indication as to the stage of the disease. It has been my experience that there is comparatively little clinical result except in the acute stages of the disease when severe "synovial" pain is present. Under these circumstances T.E.A.B. usually gives relief from pain without affecting the chronic course of the disease. Joint stiffness and swelling remain and need treatment by other methods.

St. John's Hospital,
London, S.W.11.

TREVOR H. HOWELL.

ORAL TREATMENT OF URINARY BILHARZIASIS

SIR,—Sugar-enteric-coated tablets of 'Nilodin' have proved relatively ineffective against urinary bilharziasis in young adult Africans in Southern Rhodesia.[3] Nilodin (B. W. & Co.) is a preparation of 'Miracil D' (1-diethylaminoethylamino-4-methylthioxanthone hydrochloride).

Four groups of young Africans infected with urinary bilharziasis have been treated with miracil D, miracil A, sugar-enteric-coated nilodin and plain nilodin, and an alternate-case method of treatment was used. The dose régime was 60 mg. per kg. body-weight, divided into six doses given morning and evening for three days.[4]

The patients treated were school-children, aged 6–18 years, living in a government native village outside Salisbury, and attending two schools in the village. They were treated at the end of the Rhodesian dry season, in an area where extensive copper-sulphating of streams had previously been carried out; and for many months they had been using bore-hole water exclusively, so that the possibility of recent infection was exceedingly remote. There was no selection of cases, and the laboratory staff engaged on the follow-up examinations knew neither the patients' names nor the drugs administered. The follow-up arrangements were similar to those already described elsewhere.[4] The results were as follows:

Drug	*No. of cases*	*Results*	
		Cures	*Failures*
Miracil D	40	37	3
Miracil A (Elberfeld)	28	13	15
Nilodin plain	68	62	6
Nilodin coated	68	28	40

These results need little discussion. Miracil D and plain uncoated nilodin are as effective as any known drug in the treatment of urinary bilharziasis, while miracil A is much less effective. It is impossible to escape the conclusion that sugar-enteric-coated nilodin tablets are poorly absorbed in the African gut, and that this faulty absorption is responsible for the poor therapeutic results.

I am indebted to Dr. R. M. Morris, secretary for health, Southern Rhodesia, for permission to publish this report. Thanks are due to the Medical Research Council for supplies of miracil A, and to Messrs. Burroughs Wellcome & Co. for the uncoated tablets of nilodin.

Research Laboratory,
Salisbury, Southern Rhodesia.

W. ALVES
Officer-in-charge.

THE G.P.'s EQUIPMENT

SIR,—As a profession we seem a little too fond of hackneyed words. Once it was "definitely"—and still is to some extent. Now no contribution to a medical journal is complete unless it is studded with that ugly word "integration," or embellished with various "patterns." But there is a more recent one than these, and it is the word "equipment" in its relation to the G.P. Everybody who is anybody thinks he is privileged to point out the G.P.'s deficiency in equipment as if it were some kind of malignant hypovitaminosis. Dr. Collings gave very high marks for equipment, all gleaming brightly no doubt in some smart little cabinet in the corner of the surgery. The addition of a Balkan frame or two in another corner would no doubt evoke, among the less sophisticated of our patients, much admiration.

An article by a Socialist doctor in a recent edition of an illustrated weekly, and having reference to the Collings report, showed a picture of what, in the absence of my glasses, I took to be a small heap of debris of some kind, but closer inspection revealed that it was the much-discussed G.P.'s equipment, complete down to a packet of safety-pins and a modicum of cotton-wool. Any G.P. without at least that must surely have missed his vocation.

As a student I cannot remember that great clinician, the late Prof. John Ryle, either in the wards or at out-patients, being equipped with anything except a stethoscope and a percussion-hammer, which were usually sticking out of the pockets of his long white coat. No doubt other instruments were available when needed. But unlike Dr. Collings, Dr. Ryle always deprecated what one may perhaps call the increasing "technification" of medicine.

Equipment surely includes more than the mere tools of our trade. It comprises those imponderable and abstract qualities referred to in the recent B.M.A. report on the G.P.: "inexhaustible tact, wisdom, patience, discretion, imperturbability." Osler recited all these qualities fifty years ago, as he who runs may read if he picks up *Æquanimitas*, but if we pay too much attention to all that is said about us today we shall fluctuate rapidly between a state of microcephaly and one of macrocephaly, neither of which conditions would help us or our patients.

There is one thing, however, which we should bear in mind, and that is that Socialist doctors and others of the same political faith are only too ready to bring up the failings of the G.P. as incontrovertible arguments (as they imagine) for a whole-time State medical service. Whatever we may have thought on this subject in the past, we must now all decide for once to sing the same song (and let it not be the sirens' song) and resist any such attempt *à outrance*; for there is little doubt that this issue will be raised before we are much older.

CONTINUOUS DRIP TREATMENT OF PEPTIC ULCER

SIR,—Recent correspondence on the subject of milk drips used for the alleviation of the pain of peptic ulcer, has shown that the improvement in symptoms is not likely to be due directly to an alteration in the pH.

Kinsella[1] believes that peptic-ulcer pain may be relieved by food in the following way: "The hyperæmia of digestion relieves the tension in the ulcer tissues by opening up the neighbouring capillary bed in the healthy stomach wall." Such a mechanism would explain the relief of ulcer pain by the continuous administration of milk. In my experience, pain from ulcers may be relieved by the act of retching without vomiting and also by distending the stomach; and it seems possible that here too the relief may be afforded by reduction in the turgidity of the inflamed tissues around the ulcer bed.

Bristol. J. M. NAISH.

FLUOROSCOPIC EXAMINATION OF THE CHEST

SIR,—May I, even at this late date, comment on your annotation of March 18?

While it is true that Dr. Ordway and I[2] reported in 1937 that in a study of 2500 fluoroscopic examinations of the chest 13% of the cases of tuberculosis were missed, that was not the whole story. All of the missed cases were minimal and none had physical signs. More important, I believe, was a further comment in our summary:

> "If one can assume that the X-ray examination reveals 100 per cent. of the lesions of pulmonary tuberculosis our results are: revealed by X-ray, 100 per cent.; revealed by fluoroscopy, 87 per cent.; revealed by physical examination, 36 per cent.; revealed by symptoms, 33 per cent."

Having observed the results of simultaneous fluoroscopy and röntgenography of many thousands of chests since 1927, I am inclined to believe that fluoroscopy, done well and searchingly, is nearly as revealing as a well-made röntgenogram.

SCORPION STINGS

SIR,—Last year McSorley and Perry[3] contributed to correspondence on the treatment of scorpion stings an account of a method which, they said, had long been used in parts of Africa. The method consisted in injecting emetine hydrochloride subcutaneously, either directly into the area of the sting or elsewhere on the affected limb; and they had found that the intense pain of the sting was immediately and permanently relieved.

We have since been studying the effect of emetine hydrochloride, and of other substances whose use has from time to time been advocated. Our experiments were made with albino rats and with dogs and guineapigs, into which was injected the minimum lethal dose of either crude or purified scorpion toxin prepared by one of us, mainly from *Buthus quinque-striatus*—the species most common in Egypt.

In no case did we observe any favourable effect when appropriate doses of emetine were injected; neither the pain nor the symptoms of intoxication seemed to be modified. The following drugs have also been tried: atropine sulphate; ergotamine tartrate; ergotoxine ethanesulphonate; histamine; and some anti-histamine drugs, including 'Anthisan,' 'Antistin,' 'Benadryl,' and 'Phenergan.' So far none of these has proved really effective. Atropine had no apparent effect in guineapigs and dogs, but in some rats it appeared to provide some benefit. The anti-histamine drugs have proved ineffective, except for phenergan, which eased the toxic symptoms somewhat, owing no doubt to its sedative action; this drug did not avert the animals' death. The only remedy which, under these experimental conditions, has been found to save the lives of animals is antiscorpion serum given in adequate amounts at the proper time.

Details of this work will be published later.

M. ROUSHDY.

A URETHRAL SYRINGE

SIR,—Like Mr. Wardill, who wrote last week, I dislike an opaque syringe. The syringe I described (April 8) has a clear glass nozzle, and any air entering it is readily seen in the wider expansion. When the rubber bulb becomes rough it is discarded, not because of air leaks but because sterilisation may then be less certain.

After modern prostatectomy operations bleeding should not be severe, and syringes of this type have been effectively used for more than a year to keep the catheter clear. They are easy to manipulate, and the accident which unfortunately happened in Mr. Wardill's case when using a Bigelow's evacuator has not been encountered. If more powerful suction is required than is given by this syringe, I use the glass bladder syringe which I described fourteen years ago.[1]

London, W.1. E. W. RICHES.

Obituary

ROBERT MENZIES GALLOWAY

M.D. EDIN., D.P.H.

Dr. R. M. Galloway, medical officer of health for Bolton, died on June 5, at the age of 51.

He was born in Birkenhead, and he graduated M.B. with honours from the University of Edinburgh after a distinguished academic career interrupted by service as a surgeon probationer in the first world war. Five postgraduate years in hospital appointments laid a solid foundation for his future career, and he took his D.P.H. in Manchester in 1923 and his M.D. with commendation two years later.

Possessed of a broad humanitarian outlook it was not surprising that Galloway should devote himself to public health. His apprenticeship in that service was by way of assistant posts in Bolton and with the Lancashire county council under two pioneers, the late Paget Moffat and Butterworth. In 1929 he became medical officer of health for Dewsbury, and at the beginning of 1932 he took up his present appointment at Bolton. In 1948 he was appointed lecturer in public health at Manchester University. A fellow of the Society of Medical Officers of Health, he had been president of the North West branch, and only last year as president of the county-borough group he met his fellow members in a delightful weekend at Windermere. His fondness for children and young people found expression in his work for the Bolton Lads' Club, of which he was a member of the committee and honorary medical adviser.

J. Y., V. T. T., and H. M. write: "As a sound doctor and an administrator of no mean ability and acumen, Galloway, apart from his worth as a man, was held in high esteem by his authority and his colleagues. The

influence of his education in Scotland, where he spent many of his early holidays, was reflected in a pawky yet kindly and whimsical humour. As a raconteur he was in great demand. His intimate knowledge and understanding of his fellow men could be expressed with equal fluency in the Lancashire dialect, broad Scots, Welsh, or even Irish. Of his four children his elder daughter is due to qualify soon at Edinburgh, while his elder son is in his second year at Cambridge. We know that it would have brought great joy and pride had he lived to see two of his children at least in the profession to which he had devoted his life."

ALFRED EDWARD ARTHUR CARVER

M.A., M.D. CAMB., D.P.M., D.P.H.

Dr. A. E. Carver, medical superintendent of Caldecote Hall, Nuneaton, died on May 30.

He was educated at Trent College, and Caius College, Cambridge, where he took the natural sciences tripos in 1905. Three years later he qualified from St. Bartholomew's Hospital, and he held house-appointments there and clinical assistantships at the Victoria Park Hospital and Royal Chest Hospital in London before he returned to the Midlands, where for a time he was tuberculosis officer at the Birmingham General Hospital. His practice in Birmingham was interrupted by the 1914–18 war during which he served with the R.A.M.C. in Salonika and later at Maghull Hospital. Here his interset in neurology was stimulated, and after demobilisation he became neurological specialist to the Ministry of Pensions in the West Midland region and physician in charge of the psychotherapeutic clinic at the Birmingham and Midland Hospital for Diseases of the Nervous System.

After his appointment to Caldecote Hall his interest naturally was more and more concentrated on problems of addiction and of alcoholism. In *Alcoholism in General Practice* (1936), in which he collaborated with Dr. T. C. Hunt and the late Sir William Willcox, his discussion of the treatment and aftercare of the alcoholic offered the practitioner wise and practical counsel. He emphasised that institutional treatment was the form of therapy most likely to be successful, provided the patient was willing to coöperate, a theme which he had already discussed in his first paper to the Society of Inebriety in 1926. This society (now known as the Society for the Study of Addiction) remained one of his chief interests. A member of council from 1934, he hardly ever missed a meeting, even during the war. A fellow member, describing him as an excellent lecturer with an attractive informal delivery, adds: "His approach to the problems of alcohol became increasingly psychological during his career. Those that differed from him have lost a worthy opponent."

During the late war Dr. Carver served as psychiatrist in the E.M.S., and in the early days of the blitz he suggested that an attempt should be made to condition civil defence workers against noise. He himself had some success in the application of this idea when he held "blitz concerts" in the capacious cellars of Caldecote Hall.

MORRIS YOUDELEVITZ YOUNG

C.I.E., M.B. GLASG.

Dr. M. Y. Young, medical adviser to the Anglo-Iranian Oil Company, who died on May 18, will long be remembered by the staff of the company as a counsellor and a friend.

He graduated M.B. at the University of Glasgow in 1906, and in the following year went to Persia as the first medical officer of the Anglo-Iranian Oil Company. In 1926 he transferred his headquarters to the London office as chief medical officer, and on his retirement in 1933 he was appointed medical adviser to the company.

After he retired, Young wished to work in a bacteriological laboratory and he settled down in the inoculation department of St. Mary's Hospital. Until this time he had never greatly concerned himself with the technical side of bacteriology, but by dint of his energy and application he became a skilled bacteriologist. During the second world war he worked with Dr. A. B. Porteous in the E.M.S. public-health laboratory at Ealing, where he remained until 1945, when he returned to St. Mary's Hospital as deputy director of the newly formed antibiotic unit. There he did valuable research work both in the ward and in the laboratory on the use of penicillin and on tests by which the treatment was controlled.

Sir Alexander Fleming, F.R.S., writes: "Young's long clinical experience made him especially fitted for this work, and, although he had become a laboratory worker, his real interest in life still lay in the treatment of the sick. He got an immense pleasure from the amazing results he obtained with penicillin in apparently hopeless cases and his enormous vitality and meticulous attention to detail contributed in no small measure to these successes.

"He had three outstanding characteristics. He had unfailing energy—having started a task he would work until its completion and would never acknowledge defeat, no matter how much effort or personal sacrifice it required. He was never influenced in any way by the importance or otherwise of the persons with whom he was in contact, and all received the same painstaking treatment and consideration at his hands. He never looked for personal reward. For 18 years he worked at St. Mary's Hospital and in the E.M.S. in an honorary capacity, and his unflagging devotion and keenness provided a wonderful example to the younger workers."

Dr. WILLIAM FREEMAN SNOW, president of the Union Internationale contre le Péril Vénérien, and chairman of the board of directors of the American Social Hygiene Association, died on June 12. Dr. Snow was born in 1874.

Diary of the Week

JUNE 18 TO 24

Monday, 19th

ROYAL COLLEGE OF PHYSICIANS, *Pall Mall East, S.W.1*
5 P.M. Dr. F. H. Young: Use of Collapse Therapy in the Treatment of Pulmonary Tuberculosis. (Second lecture.)

5.30 P.M. Dr. J. Marshall: Causes of *Blindness*.

MAIDA VALE HOSPITAL MEDICAL SCHOOL, W.9
5 P.M. Dr. P. H. Sandifer: *Clinical neurological* demonstration.

News

University of Oxford

On June 3, the degree of D.M. was conferred on J. M. Rice-Oxley and J. R. O'Brien.

University of Birmingham

Dr. C. White has been appointed lecturer in physiology from Sept. 1. He is at present working in the department of physiology in the University of Pennsylvania.

Royal College of Surgeons of England

At a meeting of the council of the college held on Thursday, June 8, the following were coopted to the council for 1950–51 :

Dr. Guy Dain (general practice), Prof. A. M. Claye (gynæcology and obstetrics), Mr. V. E. Negus (otolaryngology), Mr. A. D. Marston (anæsthetics), Mr. J. H. Doggart (ophthalmology), Prof. R. V. Bradlaw (dental surgery), Prof. B. W. Windeyer (radiology).

Mr. R. V. Cooke was admitted as a member of the court of examiners, and the following examiners were appointed :

Fellowship.—Ophthalmology : Dr. S. P. Meadows. Anatomy : Prof. James Whillis, Mr. P. H. Mitchiner, Prof. Thomas Nicol, Mr. D. N. Matthews. Applied Physiology and Pathology : Prof. J. H. Dible, Prof. W. R. Spurrell, Prof. D. T. Harris, Prof. Theodore Crawford.

Diploma of L.R.C.P., M.R.C.S.—Elementary Biology : Mr. Alan Fisk, Mr. Frederick Segrove, Mr. A. G. Hamilton, Mr. C. C. Hentschel. Anatomy : Prof. D. V. Davies, Mr. R. J. Last, Prof. Thomas Nicol. Physiology : Prof. D. T. Harris, Dr. C. C. N. Vass. Midwifery : Mr. H. G. Kirwan-Taylor, Mr. Henry Evers, Dr. R. K. Bowes, Mr. D. M. Stern. Pathology : Dr. J. O. Oliver, Dr. H. A. Magnus, Prof. E. F. Finch, Mr. L. E. C. Norbury.

Diploma in Public Health.—Preliminary : Dr. Ian McCracken. Final : Dr. C. O.-S. B. Brooke.

Diploma in Tropical Medicine and Hygiene.—Colonel H. E. Shortt, Prof. Sydney Smith.

Diploma in Ophthalmology.—Prof. Arnold Sorsby, Mr. R. C. Davenport, Mr. A. B. Nutt, Mr. T. K. S. Lyle, Mr. A. G. Cross, Mr. A. McKie Reid, Dr. Eugene Wolff.

Diploma in Psychological Medicine.—Part I : Dr. Louis Minski.

Diploma in Laryngology and Otology.—Part I : Prof. F. C. Ormerod, Mr. G. H. Livingstone. Part II : Mr. John Henry Cobb.

Diploma in Medical Radiodiagnosis.—Part I : Mr. F. W. Spiers, D.Sc. Part II : Dr. Hugh Davies.

Diploma in Medical Radiotherapy.—Part I : Dr. Spiers. Part II : Mr. Ivor Glyn Williams.

Diploma in Anæsthetics.—Part I : Dr. Stanley Rowbotham, Dr. J. F. Taylor. Part II : Mr. R. H. Boggon, Prof. R. R. Macintosh.

Diploma in Child Health.—Dr. A. D. C. Bell, Mr. G. H. Macnab, Mr. T. Twistington Higgins.

Diploma in Physical Medicine.—Part I : Dr. Eric John Crisp, Mr. Hubert Wood. Part II : Mr. Philip Wiles, Dr. W. S. Tegner.

Diploma in Industrial Medicine.—Part I : Dr. Arthur Massey. Part II : Dr. Hubert Wyers.

Heberden Society

The annual Heberden " round " was given by Prof. F. Coste at the Hôpital Cochin, Paris, on May 20.

Faculty of Ophthalmologists

At a meeting of the council on May 19, the following were elected officers for 1950–51 : president, Mr. Frank W. Law ; vice-president, Mr. O. M. Duthie ; hon. secretary, Mr. J. H. Doggart ; hon. treasurer, Mr. A. B. Nutt. Casual vacancies on the council, caused by the alterations to the regions represented, have been filled as follows : Oxford, Mr. G. T. W. Cashell ; Northern Ireland, Mr. J. R. Wheeler ; Liverpool, Mr. McKie Reid ; South-Western, Mr. R. R. Garden ; East Anglia, Mr. G. H. Buck ; Newcastle upon Tyne, Mr. H. Vernon Ingram. Mr. Doggart was nominated to represent ophthalmology on the council of the Royal College of Surgeons for 1950–51.

It was agreed to give general support to the following resolution sent by the British Association of Otolaryngologists to the Royal Colleges and to the Otolaryngologists Group Committee of the British Medical Association :

> The council views with concern the tendency of regional boards to appoint full-time consultants to the staffs of hospitals and maintains that such appointments should remain as heretofore predominantly part-time.

A letter was received from a member objecting to a statement in a circular issued by the Welsh Board of Health regarding second eye-tests. The member felt that the power to authorise a second eye-test within twelve months should rest entirely with the ophthalmic medical practitioner and not with the ophthalmic optician. It was agreed to make representations to the Ministry that these cases should be referred to the hospital service, whether they had been examined originally by an ophthalmic medical practitioner or an ophthalmic optician.

The faculty is continuing to sponsor study visits to clinics abroad.

Ophthalmological Society of the United Kingdom

The Edward Nettleship prize for 1950 has been awarded to Prof. A. J. Ballantyne.

Renal Association

The second general meeting of this association is to be held on June 21 at 4 P.M., at the Ciba Foundation, 41, Portland Place, London, W.1.

Italian Hospital, London

On Monday, June 19, at 3 P.M., the Italian Ambassador will reopen the Italian Hospital which was closed during the war.

Liverpool Regional Hospital Board

At a meeting on June 1, the board agreed to carry out a survey in relation to preconvalescent annexes, as desired by the Ministry of Health. Similar investigations are to be made in certain other industrial areas. The board also considered a report on possible means of economising in drugs and dressings.

International Congress of Radiology

The Earl of Athlone will open the sixth International Congress of Radiology at the Central Hall, Westminster, on July 24. Nearly 50 countries will be represented at the congress, which will be continued in a number of sections until July 28. Meetings will be held in the Central Hall, at Church House, and in the Caxton Hall. A scientific exhibition, part of which will be compiled in collaboration with the Science Museum, will take place at the Central Hall during the congress week and an exhibition of apparatus, accessories, and materials for use in radiology and physiotherapy will be held in the two halls of the Royal Horticultural Society in Vincent Square.

Society of Chiropodists

This society is holding its annual convention in London on June 22, 23, and 24 at Friends House, Euston Road, N.W.1. Sir Cecil Wakeley, P.R.C.S., will open the meeting, and other medical speakers will include : Dr. I. L. MacKinnon (Rôle of the Nervous System in the Life of the Lower Limb), Dr. J. I. Aitken (Posture in relation to Feet), and Mr. J. C. R. Hindenach (Orthopædic Aspects of the Rheumatic Diseases in Relation to the Leg and Foot).

British Association of Urological Surgeons Home and Overseas

The sixth annual meeting of the association will be held at Manchester on June 30 and July 1 under the presidency of Mr. W. W. Galbraith. The programme includes short papers, films, clinical demonstrations, and operating sessions. Mr. Hugh Donovan and Mr. F. G. Hollands will open a discussion on the Results of Diathermy Treatment of Villous Papilloma of the Bladder; and Dr. Ralston Paterson and Mr. D. S. Poole Wilson will introduce a series of papers on the Treatment of Carcinoma of the Bladder.

W.H.O. Executive Board

At the opening of the board's sixth session, in Geneva on June 1, Dr. H. S. Gear (South Africa) was elected chairman, in succession to Sir Arcot Mudaliar (India). Dr. Gear, who was born in 1903, is deputy chief health officer of the Union of South Africa, and has held various public-health appointments in China, Rhodesia, and South Africa, and with the British Army.

The board decided on May 7, 1951, as the date for the opening of the fourth World Health Assembly, which is to be held in Geneva.

National Foot Health Exhibition

Opening this exhibition in London last Monday, Sir Wilson Jameson welcomed the establishment of the Foot Health Educational Bureau, which had been the means of bringing together all those interested in preventing and treating foot defects. " The medical profession, as a whole, does not yet appreciate fully the far-reaching consequences of neglect of the feet. Parents, in particular, need educating as to the importance of buying the right sort of footwear for growing children, and I feel fairly certain that there are not a few members of the boot-and-shoe industry who fall short of the standard of knowledge and practice laid down by the best elements of the industry itself."

London County Medical Society

A clinical meeting of this society will be held at Queen Mary's Hospital, Carshalton, Surrey, on Wednesday, July 12, at 2.30 P.M. Further *information* may be had *from* Mr. J. Gabe, F.R.C.S., St. Alfege's Hospital, S.E.10.

Dental Whitley Council

A Whitley Council for Dentists employed by or in contract with local authorities has been established, and the first meeting was held on June 8. A claim for improved salaries and conditions of service has been lodged by the staff side and is under consideration.

The Board of Registration of Medical Auxiliaries

Mr. L. Vernon Cargill, F.R.C.S., treasurer and a vice-president of the board since 1937, has retired. Mr. J. H. Hanby, F.CH.S., has been appointed treasurer and Dr. A. P. Gibbons and Mr. F. Melville, hon. F.S.R., vice-presidents. Dr. F. D. Howitt, has been appointed by the Society of Apothecaries to replace Mr. Cargill.

International Congress of Gerontology

The first International Congress of Gerontology will be held at Liége from July 10 to 12 under the presidency of Prof. L. Brull, dean of the faculty of medicine of the University of Liége. During the meeting it is hoped to set up an international association of gerontological societies. Further particulars may be had from Professor Brull, Hôpital de Bavière, Liége, Belgium.

R.A.F. Medical and Dental Branch

The annual dinner of the R.A.F. Medical and Dental Branch will take place on Friday, Oct. 6, at the Hyde Park Hotel, London, at 7.30 P.M. As the number of tickets (£1 8*s*.) is limited, past and present medical officers who wish to attend should apply as soon as possible to the honorary secretary, Wing-Commander G. R. Gunn, Air Ministry (MA3), Awdry House, Kingsway, W.C.2.

Lady Tata Trust

The *trustees* of this fund have made the following awards for research in blood diseases, with special reference to leukæmia, in the year beginning on Oct. 1, 1950:

Grants for research expenses and assistance: Prof. Jørgen Bichel (Aarhus, Denmark); Dr. George Discombe (London); Dr. Astrid Fagraeus and Dr. Bo Thorell (Stockholm); Dr. Niels Gunnersen Harboe (Copenhagen); Dr. Endrev Kelemen (Szeged, Hungary); Prof. Charles Oberling (Paris); Dr. Edith Paterson (Manchester); Dr. Günther Schallock (Münster).

Scholarships: Dr. Pascou Atanasiu (Rumania) for work in Paris; Dr. Henri Paul Lucien Febvre (France) for work in Paris.

Society for the Relief of Widows and Orphans of Medical Men

The annual general meeting of this society was held on June 7, with Mr. C. J. Hope Gunning, *vice-president*, in the chair. Mr. G. T. Mullally was elected a vice-president. At the end of the year the membership of the society was 244. During the year 43 widows were in receipt of grants, and the total sum distributed was £4000. The by-law setting an income-limit for widows who receive grants has been raised from £125 to £150 per annum. Further details as to membership of the society may be had from the secretary, 11, Chandos Street, London, W.1.

Association of Sea and Air Port Health Authorities

Addressing this association at its annual meeting, held at Grimsby on June 7–9, Dr. L. Thomas, senior medical officer, London Airport, stated that both London (Heath Row) Airport and Northolt Airport were designated as sanitary aerodromes as from Sept. 23, 1949. The health control was vested in the Middlesex County Council as the authority for administering the Public Health (Aircraft) Regulations, 1950. The bulk of the passenger traffic by air into England passed through these two airports; Northolt took all the internal traffic, whereas Heath Row took the world traffic; the Continental traffic was shared between the two airports. The health-control procedure was closely integrated with the examination of passengers by the immigration and customs authorities. He described the revised procedure, under the Western Union Agreement, whereby medical inspection is limited to the first port of entry within the union. At this examination the personal health declaration is stamped red or green. The red stamp indicates that further health surveillance is necessary, whereas the green stamp normally frees the passenger from further inspection or health control.

Appointments

BELL, H. E., M.B. N.U.I., D.A.: anæsthetist (registrar), Edinburgh central group of hospitals.

CASSELLS, JOHN, M.B. Glasg.: deputy superintendent, Gogarburn Institution for Mental Defectives.

GOLD, S. C., M.B. Camb., M.R.C.P.: hon. dermatologist, Hospital of St. John and St. Elizabeth, London.

GROOM, W. A., L.M.S.S.A., D.A.: senior registrar anæsthet St. Andrew's Hospital, London.

MURPHY, MONICA, M.B. Glasg., D.OBST.: obstetric and gynæcological registrar, St. Andrew's Hospital, London.

VAUGHAN, C. J. R., M.R.C.S.: M.O. Colonial Service, Somaliland.

Appointed Factory Doctors:

CARMICHAEL, LACHLAN, M.B. Glasg.: Saltcoats district.

HERFORD, M. E. M., D.S.O., M.C., M.B.E., M.B. Brist., D.P.H.: Windsor and Slough district.

LODEN, A. E., M.B.E., M.B. Lond.: Horsmonden district.

Liverpool Regional Hospital Board:

FRANCIS, W. J. L., CH.M Glasg., F.R.C.S., M.RAD. Lpool, D.M.R.T.: consulting radiotherapist, Liverpool Radium Institute.

GOLDSTEIN, DAWID, M.D. Cracow: [illegible] duties in Liverpool and clinics in ..

ROBINSON, W. A. M., M.B. Lpool, D.P.H.: [illegible] Rainhill Hospital.

SCARROW, G. D., M.B. Lpool, M.RAD., D.M.R.D.: consulting radiologist, hospitals in Wirral.

THOMAS, R. G., M.B. Lpool, D.P.H.: asst. S.M.O., regional hospital board.

Births, Marriages, and Deaths

BIRTHS

BALL.—On May 30, in London, the wife of Dr. Keith Ball—twin daughters.

BELILIOS.—On June 3, at Wimbledon, the wife of Dr. A. D. Belilios—a daughter.

CAMPBELL.—On June 3, at Clifton, Bristol, the wife of Dr. A. M. G. Campbell—a son.

CHALMERS.—On June 2, in London, the wife of Dr. J. N. Marshall Chalmers—a son.

DALE.—On May 29, at Taipeh, Taiwan, the wife of Dr. H. Donald Dale—a son.

GREGORY.—On June 1, at Guildford, the wife of Dr. Basil Gregory—a son.

HUGHES.—On June 8, in Bristol, the wife of Dr. E. Brierley Hughes—a daughter.

HUNT.—On May 31, at Blackpool, the wife of Dr. G. N. Hunt—a son.

MANT.—On May 30, in London, the wife of Dr. A. Keith Mant—a daughter.

SANDS.—On June 3, in London, the wife of Dr. Richard Xerxes Sands—a daughter.

SLOVICK.—On June 4, in London, the wife of Dr. David Slovick—a daughter.

MARRIAGES

HALL—CAPNER.—On June 5, Surgeon Vice-Admiral Sir Basil Hall to Mrs. Dorothy Capner.

LEECH-WILKINSON—COOMBS.—On June 3, at Bathwick, Arthur Leech-Wilkinson, F.R.C.S., to Janet Elizabeth Coombs.

DEATHS

EWART-JONES.—On June 4, at Folkestone, Philip William Ewart-Jones, B.SC. Wales, M.R.C.S.

GILCHRIST.—On June 4, at Shere, Surrey, John Gilchrist, M.D. Edin.

MEADEN.—On May 26, at Thetford, the Rev. Charles Anderson Meaden, M.R.C.S.

PORTER.—On June 4, at Falmouth, Frederick Joseph William Porter, D.S.O., M.R.C.S., major, R.A.M.C. retd, aged 83.

SLATER.—On June 3, in London, Alan Butler Slater, M.D. Edin., aged 75.

TATTON.—On May 29, in Edinburgh, Glyde Philip Tatton, M.B. Lond.

CORRIGENDUM: *Foresight in the U.S.A.*—Our annotation of March 25 implied that the United States, in 1940, *had far* larger "physician resources" than was in fact the case. We said: "*In 1940* a quarter of the inhabitants *of the* United States lived in regions which had 146 or more doctors per *100,000*; *a* third lived in regions with a doctor-patient ratio below 146 but above 136; and the remainder lived in *areas* with a ratio below 136 but above 118." *Closer study* of the U.S. Public Health Bulletin no. 305, which we were reviewing, shows that not quite half the population *lived* in regions with *118 doctors, or more, per* 100,000 *population.* Of these regions, numbering 37, the top 16, with a minimum doctor-patient *ratio of* 136, contained a third of the population, and the top 12, with a minimum ratio of 146, contained a quarter. *What our annotation did not make clear* was that in the remaining 89 regions, inhabited by the other half of the United States *population*, ratios were below 118 per 100,000, ranging from 56·8 upwards.

THE EXPERIMENTAL BACKGROUND AND CLINICAL USE OF ANTIBIOTICS *

From the Department of Preventive Medicine, The Johns Hopkins University School of Medicine, Baltimore

TODAY, the practitioner of medicine will be found wanting unless he understands clearly the experimental background for the clinical use of the many antibiotics which are, or soon will be, at his disposal. To serve efficiently his patient who is suffering from an infectious process, he must choose that antibiotic which experimental and clinical experience has shown to be best for that particular infection. His knowledge must be such that he unerringly administers the antibiotic of choice.

Five years ago this was easy: one recommended the use of penicillin if it appeared to be indicated. Four years ago the situation became more complicated owing to the introduction of streptomycin, an antibiotic which is highly effective not only against many gram-negative bacillary organisms but also against certain gram-positive ones. But even then the choice of antibiotics was not too difficult. Now the situation has changed. One has the choice of bacitracin for use in limited spheres, or of aureomycin, chloramphenicol ('Chloromycetin'), or terramycin in a wide variety of infections; and polymyxin, neomycin, and viomycin may soon emerge over the clinical horizon. Other effective antibiotics will undoubtedly be discovered, and, with each new therapeutic agent of this type, the practitioner's problem of choosing the right one for the treatment of his patient becomes more complex.

However, this multiplicity of antibiotics is all to the good, at least as far as the patient is concerned. The increasing range of efficacy of these agents against infectious processes, the ease with which they can be administered, and the certainty of their beneficial action have completely altered the medical, social, and economic aspects of infectious diseases. In most instances the practitioner can confidently assure a patient who is suffering from an infection that he will be well in a short time. This undoubtedly improves the relations between the practitioner and his patient. The latter benefits socially and economically by frequently being spared the costs of catastrophic illness, and, since certain of the antibiotics such as aureomycin are admirably suited for home use, the costs of hospital and other medical care are often avoided. Furthermore, with the development of new antibiotics and with an increase in our knowledge of possible prophylactic uses for these agents, they are becoming exceedingly valuable in preventing certain infectious processes from developing after exposure has taken place, and in minimising the seriousness of others. Thus the proper choice and use of antibiotics for the control and treatment of infections assumes a very important rôle in the practice of medicine, because they concern not only the life and well-being of the patient but even his social and economic status. This paper presents relevant data from our own laboratories and our own clinical experience.

The Experimental Background

TOXICITY

While experimental testing of the toxicity of antibiotics in mice, white rats, and dogs does not provide information about the reactions of sensitivity which these agents may produce in human beings, it does provide useful information about the direct lethal and organic toxicities of these substances. Because they are well known, the acute and chronic toxicity of penicillin and streptomycin will not be discussed here.

The acute toxicities for mice, following the subcutaneous injection of the newer compounds as measured by the lethal dose for 50%—i.e., that dose which will kill half the mice—are as follows: for polymyxin D, 250–300 mg. per kg. body-weight; for aureomycin, 3000–4000 mg. per kg.; for chloramphenicol, 1300 mg. per kg. (by the intraperitoneal route); for neomycin, 450 mg. per kg.; and for terramycin, 600–650 mg. per kg.

Young female white rats have been useful in determining whether new antibiotics may produce renal damage. It was found that, when aureomycin or terramycin was administered to white rats in doses of 50–200 mg. per kg. for a period of ten days, no renal changes took place. On the other hand, the administration to white rats of polymyxin D in doses of 10–20 mg. per kg., or of neomycin in doses of 30–60 mg. per kg., produced definite evidence of renal damage.

Further studies of the acute and subacute toxicity of antibiotics were made in dogs. From these animals additional information has been obtained concerning the renal toxicity of polymyxin D and neomycin. Polymyxin D in doses of 40 mg. per kg. for ten days produced definite injury in canine kidneys. The damage was tubular in nature. With neomycin in doses of 80 mg. per kg. for ten days, renal damage was noted in dogs, and in one instance this amount of the antibiotic appeared to

TABLE I—IN-VITRO BACTERIOSTATIC ACTIVITY OF ANTIBIOTICS AGAINST CERTAIN GRAM-POSITIVE MICRO-ORGANISMS (μG. PER ML.)

cause deafness. Thus it can be seen that studies of the acute toxicity provide indications for the dosage of antibiotics in experimental and clinical therapy, as well as information on direct organic damage which may be done by these agents.

ANTIBACTERIAL EFFECTS IN VITRO

A general knowledge of the types of antibacterial effects, coupled with information on the degree of activity of antibiotics in vitro, is useful to the practitioner. He should know whether a given antibiotic has a primarily bactericidal or primarily bacteriostatic effect against micro-organisms. This knowledge permits him to gauge more accurately the dosage and duration of therapy. The antibacterial activity of a number of antibiotics in vitro is shown in tables I and II.

It is to be noted that penicillin G is the most effective antibacterial agent against gram-positive micro-organisms in vitro, and that aureomycin and terramycin are close seconds. Chloramphenicol and streptomycin possess some antibacterial activity against gram-positive micro-organisms, but on the whole much less than that of the three antibiotics first mentioned.

When the antibacterial activity in vitro of certain of the antibiotics against gram-negative micro-organisms is tested, polymyxin D, terramycin, and neomycin appear to be comparable in their effects (table II). Aureomycin and chloramphenicol are also similar in their antibacterial activity. There is one interesting thing—namely, that neither of these latter two antibiotics is highly bacteriostatic against *Pseudomonas aeruginosa* (*Ps. pyocyanea*, var. *erythrogenes*) and their activity against organisms of the proteus groups is quite variable.

It is fair to ask how far these in-vitro observations can be carried over to the experimental and clinical treatment of infections. The answer is more or less. While terramycin and aureomycin have about the same bacteriostatic activity in vitro, the latter is more effective against experimental pneumococcal and streptococcal infections in mice. Similarly, while polymyxin D, aureomycin, and chloramphenicol have a high degree of antibacterial activity against *Salmonella typhi* in vitro, of the thre chloramphenicol alone has proved to be of real value i the treatment of typhoid fever. In the therapy of gram negative bacillary clinical infections due to *Bacterium col* *Bact. aerogenes*, *Brucella abortus*, *Bact. pneumoniæ*, c *Bact. tularense*, aureomycin and chloramphenicol seem t be comparable. Their bacteriostatic activity agains these micro-organisms in vitro is about the same. I would appear then that while generalisations can b made from in-vitro activity (and most certainly from lack of activity), in any specific instance, the data fro such studies do not enable one to predict with certaint what the curative effects of a given antibiotic will be i all experimental or clinical infections.

10	30	..	40	..	0	0
5	20	..	2·5	..	..	0
2·5	20	..	0	..	..	..
0·8	0	..	..	..	..	..
0·0	0	0	0	0	0	0

* Drug administered subcutaneously statim, 5½, and 23 hours after infection.

Investigations in our laboratories over a period of years permit us to say, within certain broad limits, that, in vitro, polymyxin D is highly bactericidal, that penicillin G is moderately bactericidal, and that aureomycin, chloramphenicol, terramycin, streptomycin, and neomycin are highly bacteriostatic.

BACTERIAL RESISTANCE

The problem of bacterial resistance to the antibacterial effects of antibiotics is becoming important. Reports concerning the isolation of penicillin-resistant strains of *Staphylococcus aureus* as the ætiological agents in hospital epidemics or endemics of staphylococcal infection are increasing. Romansky (1950) reports that, in 1949, 58% of the strains of *Staph. aureus*, 21% of the strains of *Staph. albus*, 55% of the strains of non-*hæmolytic* streptococci, and 98% of the strains of *Strep. fæcalis*, which he isolated from infectious processes, showed primary resistance, of varying degree, to the antibacterial effects of penicillin. Strains of hæmolytic streptococci (group A), pneumococci, and meningococci which he tested in the same year were not resistant. Similarly, 33% of the strains of *Bact. coli*, 45% of the strains of *Bact. aerogenes*, 70% of the strains of proteus, 77% of the strains of *Ps. aeruginosa*, 33% of the strains of non-hæmolytic streptococci, and 77% of the strains of *Strep. fæcalis* which he isolated from infectious processes were primarily resistant to the antibacterial effects of streptomycin.

Studies in our own laboratories seem to demonstrate that susceptible micro-organisms seldom if ever develop "step-like" resistance to aureomycin. It is possible to produce temporarily twofold, fourfold, or eightfold increases in the resistance of certain micro-organisms to aureomycin, but first-generation increases of a thousandfold or ten-thousandfold in resistance have not been observed. Also the slight increases noted in resistance to aureomycin in vitro tend to disappear promptly in subsequent generations after the exposure to the antibiotic has ceased.

TREATMENT OF EXPERIMENTAL INFECTIONS

This phase of the investigation of an antibiotic is the one which gives valuable information about its potential activity in the treatment of infections in human beings. While a wide variety of infections may be produced in mice by infectious agents derived from human sources, certain standard infections, the natural history of which are well known, are usually employed for this purpose. In our own laboratory for more than ten years experimental infections (peritonitis) in mice produced by a strain of β-hæmolytic streptococci (C 203), a strain of type I pneumococcus (SV 1), a strain of Friedländer's bacillus (type A), and a strain of influenza bacillus (type B) have been used for determining the therapeutic effects of antibiotics. The concomitant injection of mucin to produce infections of the desired virulence is needed only with the strain of the influenza bacillus. The results of therapeutic tests with various antibiotics in experimental infections in mice are given in tables III–VI.

A study of these carefully controlled therapeutic experiments indicates that, for infections produced in mice by strains of gram-positive cocci, the most effective agents were penicillin G, aureomycin, terramycin, and chloramphenicol—in the order named. In infections produced by strains of Friedländer or influenza bacillus, polymyxin D, neomycin, streptomycin, and terramycin were almost equally effective, aureomycin and chloramphenicol being somewhat less so. It is also to be noted that aureomycin is the most effective antibiotic for the over-all treatment of all four types of infection. These results in the treatment of infections in mice have been amply confirmed by the results obtained in treating similar infections in human beings. Because of this experience, we believe that a knowledge of the results obtained with any given antibiotic in the treatment of experimental infections is essential if the antibiotic is to be properly used in clinical medicine.

TABLE V—EFFECTS OF ANTIBIOTICS IN EXPERIMENTAL FRIEDLÄNDER'S BACILLARY INFECTIONS IN MICE

Friedländer's A. 1000–10,000 M.L.D. injected intraperitoneally. Ten to twenty mice in each group.

* Drug administered subcutaneously statim, 5½, and 23 hours after infection.

PHARMACOLOGY OF ANTIBIOTICS

The pharmacology of penicillin and streptomycin will not be described, because practitioners are quite aware of the behaviour of these agents in the human body. Of the newer antibiotics, polymyxin D and neomycin will be omitted from discussion because of the uncertainty that they will ever become generally available to practitioners, owing to their organic toxic properties. We shall deal here with only aureomycin, chloramphenicol, and terramycin.

Aureomycin

When aureomycin is administered by mouth in a single dose of moderate size, the maximal absorption, as measured by its concentration in the blood-serum, appears to take place in from two to six hours, and detectable quantities of the antibiotic may be present in the blood-stream for at least twelve hours. The antibiotic has been noted in emulsions of the liver, kidney, spleen, and lungs of patients who died while receiving it; but nothing is known as to whether it actually diffuses into the intracellular water of the cells of these tissues. We suspect, however, that it does, and certainly it must penetrate the endothelial cells: otherwise it would be difficult to explain the action of aureomycin on rickettsia. This antibiotic does not easily pass the blood-brain barrier in human beings, but when the meninges are infected it can be detected in the cerebrospinal fluid. It passes into the bile and milk in fair concentrations. As yet we do not know whether it diffuses into the vitreous or aqueous humour. From 12 to 15% of a single dose of aureomycin can be recovered from the urine, in which it may be excreted for as long as seventy-two hours after a single dose. In the urine, concentrations of several hundred microgrammes of aureomycin are easily obtainable after moderate and repeated doses of aureomycin. It passes the placental barrier, and appreciable amounts can be detected in the cord blood of the infant when the mother is receiving aureomycin. With multiple doses of aureomycin spaced at six-hourly intervals, concentrations of 2·5 to 20 μg. of the antibiotic per 100 ml. have been noted in the blood-stream.

TABLE VI—EFFECT OF ANTIBIOTICS IN EXPERIMENTAL INFLUENZAL BACILLARY INFECTIONS IN MICE

H. influenzæ type B. 100–10,000 M.L.D. injected with mucin intraperitoneally. Ten to thirty mice in each group.

1	55	83	25	0	13	0
0	0	0	0	0	0	0

* Drug administered subcutaneously statim, 5½, and 23 hours after infection.

It appears that after an intravenous dose of aureomycin maximal concentrations of the antibiotic in the blood are reached within five minutes, while detectable amounts may be noted for as long as twelve hours. Also it has been observed that relatively small amounts of aureomycin, when injected by the intravenous route, will produce excellent concentrations of the antibiotic in the patient's blood. This observation is of importance to the physician when he is considering the use of aureomycin in critically ill patients.

It can be seen from this that much is unknown about the pharmacology of aureomycin, and further progress in this field awaits the determination of its chemical structure. However, it seems that it is quite well absorbed when given by mouth, is probably distributed in both the extracellular and intracellular tissues, and is excreted mainly in the urine ; also that the greater part of a dose of aureomycin, as such, is destroyed in the body. There is no evidence that renal dysfunction lessens its excretion in the urine.

Chloramphenicol

Chloramphenicol is a crystalline antibiotic which, in chemical structure, is a nitrobenzene compound. It can be produced by a synthetic method. It is relatively insoluble, and for that reason oral administration is preferred. When a single moderate dose of chloramphenicol is given by mouth, the concentration of the antibiotic in the blood reaches a peak within two hours and then declines ; at eight hours its presence is often no longer detectable.

Though extensive studies have not been made, it seems that chloramphenicol is well distributed in the body tissues. It undoubtedly is present in both the intracellular and extracellular body water : otherwise it would not be so effective in the control of rickettsial infections. It readily passes into the cerebrospinal and pleural fluids and it is found in appreciable quantities in the bile. The placenta offers no barrier to its passage and within two hours of the administration of a single dose the concentration of chloramphenicol in cord blood is approximately 75% of that in the maternal blood. It is excreted mainly in the urine, in which it appears in appreciable quantities within thirty minutes of a single dose. With multiple doses of chloramphenicol there is little difficulty in maintaining high concentrations of the antibiotic in both blood and urine. It is not yet known whether chloramphenicol passes into the vitreous or aqueous humours.

Both chemical and biological tests are available for detecting chloramphenicol and its breakdown products in body-fluids and tissues. A comparison of the two tests, on like samples of blood from patients who are receiving chloramphenicol, shows that in the first few hours after the antibiotic has been administered both tests give comparable readings. Then, however, the chemical values mount, while the biological values drop, indicating the conversion of chloramphenicol to an inactive form in the body. In the urine this difference is always very marked and the chemical test gives readings about ten times greater than those of the biological test, again indicating that most of the chloramphenicol excreted is in an inactive form. There is no evidence that renal dysfunction impairs the excretion of chloramphenicol in the urine.

Terramycin

When terramycin is administered in a single dose of 2·0 g. to fasting individuals, it can be found in the blood-serum within thirty minutes and may remain detectable for more than twenty-four hours. In this respect terramycin differs from either aureomycin or chloramphenicol. During the twenty-four hours following the injection of a single dose of terramycin, 12–25% or more may be recovered in the urine. The antibiotic passes over into the bile in goodly quantities. It traverses the placental barrier and can be found in fœtal blood. It passes into the milk. And in normal individuals it passes, in small amounts, into the spinal fluid. Data on its general distribution in the body are still lacking.

Clinical Use of Antibiotics

THE ANTIBIOTIC OF CHOICE

Having sketched the background of experimental work, we shall now attempt to summarise current thought concerning the selection and use of antibiotics. (We shall confine ourselves to the systemic use of antibiotics, because we think that their employment as topical agents is generally unnecessary and often dangerous. Sensitisation to an antibiotic can most readily be produced by its local use.)

The subject is dynamic : what is first choice today may not be recommended at all a year hence—so rapidly is work progressing. But though our recommendations, presented in tables VII–XI, are liable to revision as experience increases or new antibiotics are developed, there are nevertheless certain fundamental rules which the physician should bear in mind :

1. Adequate doses should be employed. The aim should be to bring the infection under control as quickly as possible. This is especially important in the treatment of severe or fulminating infections.

2. Do not overtreat the patient. Antibiotics are often expensive, and all of them can produce toxic reactions. Watch carefully the clinical and laboratory response of the infection to therapy, and when in your opinion the infection is controlled discontinue treatment.

3. Remember that in most instances the response should be prompt. As a rule, if definite clinical improvement is not evident within one to three days, the physician should question the value of further therapy with the particular antibiotic he is using in the particular case.*

Necessarily this last statement must be qualified by a knowledge of the natural history and pathological nature of the infection. Infectious processes of soft tissues which are of short duration generally clear up quickly; while those in bone, in thrombi, and in certain other tissues require longer exposure to the antibiotic agent. It is also important to know whether the antibiotic has a bactericidal or a bacteriostatic action against the agent causing the infection. If the action exerted is bactericidal, the therapeutic response is generally very prompt; while if it is bacteriostatic, the response may be slower and treatment must be more prolonged. *Here, too, thought must be given to the phenomena* associated with a natural recovery from the particular infectious process, especially in relation to immune responses. When certain infectious diseases are treated very early in their evolution, and therapy is discontinued as soon as a good response to treatment has been obtained, there may be a rapid relapse because immunity has not developed.

4. While infecting micro-organisms frequently, and often quickly, develop "step-like" resistance to streptomycin, and less frequently to penicillin, they seldom develop a similar resistance to aureomycin or chloramphenicol.

5. In severe or fulminating infections, if two or more effective antibiotics are available, use them simultaneously. The aim of all antibiotic therapy is to bring the infection under therapeutic control as speedily as possible.

6. Don't give antibiotics "on a hunch that they might do some good." Use them only when there are indications that their administration is a rational procedure. Only too often antibiotics are employed without any logic for their use. This practice increases the cost of medical care to the patient or taxpayer, increases his chance of becoming sensitised to the antibiotic, and does no-one good.

PROPHYLACTIC USE OF ANTIBIOTICS

As the range of effectiveness of antibiotics against infections has been increased by the discovery of new agents, so too have the uses of antibiotics in the prophylaxis of infections. These uses are portrayed in table XII. Of especial interest are the following:

The administration of 300,000 units of crystalline penicillin G by mouth, or of 300,000 units of procaine penicillin G by the intramuscular route, will markedly decrease the incidence of gonorrhœa in those exposed to the chance of this infection.

The prompt administration of 600,000 units of procaine penicillin G in oil, with 2% aluminium monostearate added, will decrease the incidence of syphilis in those exposed to this infection.

In closed communities, crystalline penicillin G, given by mouth, can be used in the prevention of β-hæmolytic streptococcal or meningococcal infections.

Aureomycin given by mouth in doses of 2 g. a day for three or four days appears to be highly effective in the prophylaxis of puerperal infection.

In rheumatic subjects the intramuscular administration of procaine penicillin G before and after the extraction of teeth, the removal of tonsils, or for that matter any operative procedure around the nose or throat will

materially aid in preventing the development of subacute bacterial endocarditis.

The same is true when, before operations on the large bowel in older patients, streptomycin is given orally, with sulfasuxidine, to decrease the flora in the large bowel. Antibiotics, alone or with certain sulphonamides, are also useful when operating on patients with perforating abdominal wounds, and in operating on the lung.

The risk of infection after certain "clean" operations—e.g., for cataract—is much decreased by prophylactic use of antibiotics. In established infections, in which surgical interference is indicated, the proper use of antibiotics will greatly facilitate the control of postoperative spread of the micro-organisms.

There can be little doubt that the intelligent use of antibiotics has been an important factor in the improvement of the results of many surgical procedures over the past few years.

DOSAGE

We shall not spend much time here on the dosage of the various preparations of the antibiotics; for this subject is generally understood. A few points, however, are worth discussing.

Penicillin

Now that procaine penicillin G has been introduced, the use of crystalline penicillin G can ordinarily be reserved for certain severe infections. When employed, it should be given in doses of 25,000 units and upwards by the intramuscular route, at intervals of three hours day and night, until the infection is controlled.

Among the procaine penicillins, the preparation of 300,000 units of procaine penicillin G which has 100,000 units of crystalline penicillin G added to it is one of the most valuable. This may be given by intramuscular injection in aqueous suspension in doses of 300,000 units or more at intervals of eight to twelve hours. It combines the features of continuous and intermittent therapy and is a good preparation to use in many severe and almost all moderate cases of infection which are susceptible to the antibacterial action of penicillin. It also produces relatively few reactions.

A less desirable preparation of procaine penicillin G is that in vegetable oil with 2% aluminium monostearate added. The usual dose, given by the intramuscular route, is 300,000–600,000 units. As the release of the penicillin in the tissues is greatly slowed, detectable (but not necessarily therapeutic) levels of penicillin are found in the blood for about three days after the administration of a single dose. This preparation can be used in the prophylaxis of certain infections, in the treatment of mild infections which are susceptible to the effects of penicillin, and especially in syphilis. As a rule, in infections other than syphilis, procaine penicillin G in oil with aluminium monostearate added may be administered by the intramuscular route at intervals of forty-eight to sixty hours.

The use of penicillin by mouth for the treatment of severe, moderately severe, or even mild systemic infections is not recommended. It is the least desirable way of administering penicillin, and an expensive one.

Streptomycin

At present, it is believed that dihydrostreptomycin offers no special advantages over streptomycin in the doses in which these compounds are now given, and there is little use for either except in tuberculosis. This statement is made because micro-organisms rapidly become resistant to the antibacterial effects of both these antibiotics, and because both may produce serious and lasting toxic reactions. In the treatment of tuberculosis both are employed in dosages much lower than formerly. Thus, in tuberculosis other than miliary and/or meningeal, the recommended dose is now 0·5 g. of either compound by intramuscular injection twelve-hourly for at least forty-two days. In miliary or meningeal tuberculosis, 0·75 g. of the antibiotics is given twelve-hourly for ninety to one hundred and twenty days. It is currently considered advisable in tuberculosis to use *p*-aminosalicylic acid (P.A.S.) in conjunction with streptomycin. In adults the daily dose of P.A.S. is 10–12 g., and it should be given in a flavoured alkaline menstruum.

TABLE XIII—DOSAGE SCHEDULES FOR AUREOMYCIN AND CHLORAMPHENICOL

Severity of illness	*Aureomycin*		*Chloramphenicol*	
	Initial dose (mg. per kg.)	Total daily maintenance dose (mg. per kg.)	Initial dose (mg. per kg.)	Total daily maintenance dose (mg. per kg.)
Moderate (oral route) ..	None	20–30	60	60
Severe (intravenous route*)	10	20–30	..	..
Severe (oral route)	10	50	60	60–120

When the oral route of administration is being used, the calculated total daily maintenance dose is divided into 4 parts and is given at *intervals of 6 hours.*

* When aureomycin is being administered by the intravenous route, do not give more than 300 mg. in any single dose. The intravenous doses should be spaced at intervals of 8 hours. A shift should be made to treatment by mouth as soon as possible.

TABLE XIV—IMPORTANT TOXIC REACTIONS IN THE COURSE OF ANTIBIOTIC THERAPY

Mouth lesions (oral administration) ..	Common	0	Occurs	Common	Common

ureomycin and Chloramphenicol

As will be noted from table XIII, dosage schedules for ureomycin and chloramphenicol are well established. Vith aureomycin, in severely ill patients treated by the ral route, the initial dose should be based on 10 mg. er kg. body-weight. For moderately ill patients the total aily maintenance dose by mouth is based on 20–30 mg. er kg., and for seriously ill patients it is based on 50 mg. er kg. In either instance the total daily maintenance ose is divided into four parts, one of which is given every ix hours. If it seems desirable, in seriously ill patients, o initiate treatment by giving aureomycin intravenously, he sodium glycinate preparation should be used. The nitial dose should be based on 10 mg. per kg. body-veight, while the total daily maintenance dose is based n 20–30 mg. per kg. The latter is divided into thirds, ne of which is given every eight hours. But not more han 300 mg. of aureomycin should be given in one dose ntravenously.

With chloramphenicol, the initial or "priming" dose s based on 60 mg. per kg. This is divided into thirds, given at hourly intervals by mouth. The total daily naintenance dose is based on 60 mg. per kg. for moderately ll patients, and 60–120 mg. per kg. for seriously ill patients, divided into four parts, one of which is given by mouth every six hours. So far, no commercially available preparation of chloramphenicol has been developed for parenteral use. Neither aureomycin nor chloramphenicol should be given by the intrathecal route.

Terramycin

Terramycin is administered by mouth. Currently (and this recommendation may well be changed as our experience increases) it is believed that moderately ill patients should receive a total daily dose based on 25 mg. per kg. body-weight. This may be divided into fourths, one of which is given every six hours. The dosage of terramycin for seriously ill patients has not been definitely established, but a reasonable basis for the total daily dose is 40–50 mg. per kg.

TOXICITY

The toxic reactions which may follow the administration of penicillin, streptomycin, or dihydrostreptomycin are well known. Reactions due to the sensitisation of patients to these three antibiotics seem to be increasing, and it should be borne in mind that dihydrostreptomycin and streptomycin can cause permanent vestibular damage and permanent deafness.

As will be noted from table XIV, the important reactions produced by aureomycin are nausea, vomiting, and loose stools (often amounting to a diarrhœa). It is believed that the nausea and vomiting are produced partly by an exogenous factor in the preparations of aureomycin at present available for administration by mouth. The looseness of the bowels results from disturbance of the bacterial-metabolism in the colon due to the suppression of bacterial growth in that organ. Localised dermatitis has been noted when aureomycin ointment is being used, and a scaly or acneiform type of dermatitis has occasionally been reported when aureomycin was being administered. Drug fever has been noted rarely.

Chloramphenicol produces nausea, vomiting, and often looseness of the bowels, but to a less degree than aureomycin. A scaly skin eruption and drug fever have been observed during treatment, and so has granulocytopenia, both granulocytic and erythrocytic series being hypoplastic.

Terramycin gives rise to nausea, vomiting, and diarrhœa in a proportion of patients. The severity of the signs and symptoms seems to depend somewhat on the size of the dose. Skin eruptions and drug fevers have been recorded. Terramycin, aureomycin, and chloramphenicol can all cause irritation of the mouth and tongue with soreness and ulceration. Renal injury or damage to nervous tissue has not yet been reported in patients receiving these three antibiotics.

Conclusion

Owing to its widespread (and often very injudicious) use, reactions to penicillin are rapidly increasing in numbers and in severity. Streptomycin and dihydrostreptomycin may produce permanent vestibular dysfunction and/or deafness; and as there are better and less toxic antibiotics for other types of infections, their use should be limited to tuberculosis. To date, aureomycin and terramycin have been relatively non-toxic, if nausea, vomiting, sore mouth, and diarrhœa are excluded from consideration. Chloramphenicol is known to cause granulocytopenia and therefore might cause agranulocytosis. It is too early to say whether the population will become as reactive to these last three antibiotics as it has to penicillin. Only time will tell. But we should remember that, up to the present, *all antibiotics have proved poisonous to some patients*, and we should use them with care and thought.

CONTROLLED CIRCULATION WITH HYPOTENSIVE DRUGS AND POSTURE TO REDUCE BLEEDING IN SURGERY

PRELIMINARY RESULTS WITH PENTAMETHONIUM IODIDE

G. E. HALE ENDERBY
M.A., M.B. Camb., D.A.
ANÆSTHETIST, ROYAL NATIONAL ORTHOPÆDIC HOSPITAL; METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL; AND PLASTIC AND JAW UNIT, BASINGSTOKE

THE satisfactory performance of many surgical operations depends on a moderately dry field, and in some—e.g., fenestration and certain plastic operations—bleeding of any severity may well be disastrous. In such circumstances the anæsthetist will be of great assistance to the surgeon if he can safely lower the patient's blood-pressure sufficiently to reduce bleeding to a minimum, and the patient will benefit accordingly.

Hypotension is a well-recognised feature of spinal analgesia but it need not be feared if steps are taken to prevent its ill effects by correct posture of the patient and other measures. Griffiths and Gillies (1948) have shown that considerable falls in blood-pressure may safely be produced by a spinal block high enough to paralyse the thoracic sympathetic outflow. They find that an adequate circulation can be maintained during extreme hypotension; a systolic blood-pressure of about 60 mm. Hg (Dr. J. Gillies, personal communication) will maintain a capillary circulation sufficient for cellular respiration and metabolism in all the vital organs provided the blood is well oxygenated and provided vasodilatation is ensured; whereas in cases of extreme hypotension with vasoconstriction—e.g., after severe blood-loss and the administration of vascoconstrictors—arteriolar constriction reduces the capillary circulation and hastens the onset of permanent damage. Griffiths and Gillies produce vasodilatation and hypotension by a combination of total sympathetic block, narcotics, and posture, gravitational pooling of the blood in the dilated vessels being an essential feature.

An attempt has been made to produce the same effect with pentamethonium iodide and other drugs of this group which paralyse the autonomic ganglia, so avoiding many of the dangers inherent in the spinal technique.

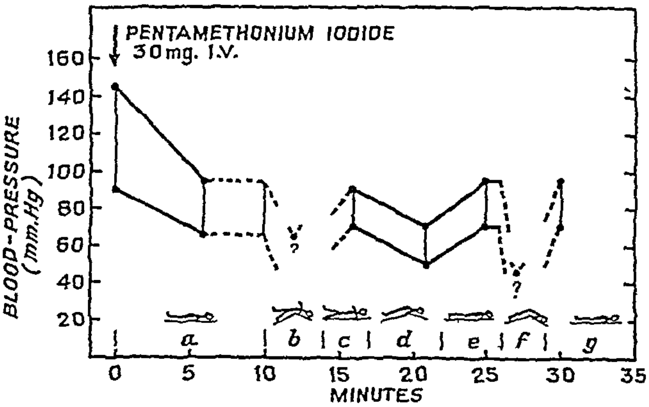

Fig. 1—Effect of posture on blood-pressure of anæsthetised healthy male, aged 40, after pentamethonium iodide, showing importance of gravitational pooling of blood in legs in production of hypotension. Blood-pressure before operation was 125/75 mm. Hg. A minor operation on the foot was completed in 30 minutes. Blood-pressure at end of operation and at start of investigation was 145/90 mm. Hg.

Postures: *a* and *g*, supine horizontal; *b*, right lateral jack-knife; *c*, right lateral horizontal; *d*, supine hyperextended; *e*, prone horizontal; *f*, prone jack-knife.

None of the available drugs completely reproduces the effects of a total sympathetic block—a fact which has been confirmed by workers in other fields, particularly by those investigating vascular disorders of the extremities (Mr. H. J. Seddon, personal communication) —and it is important to bear in mind that these drugs block both sympathetic and parasympathetic ganglia; they are not pure sympathetic paralysants.

RESULTS

First the effects of pentamethonium iodide were studied in anæsthetised subjects. A drop in blood-pressure of variable amount was usually observed, but wide variations in dose produced little difference in the resulting hypotension. In the healthy adult with a normal circulatory system it was found impossible to obtain a reduction of more than 15–30 mm. Hg in the systolic and about half that fall in the diastolic pressure. Furthermore, there was a well-marked rise of pulse-rate, probably accompanied by an increased cardiac output which maintained the blood-pressure. An investigation of tetraethylammonium chloride and hexamethonium iodide did not reveal any material difference; indeed pentamethonium iodide proved slightly more effective than the others. However, Smith et al. (1939) have shown that spinal block in the "unoperated-on subject in the horizontal position" produces no change in diastolic and very little in systolic pressure. It seems, therefore, that in the technique used by Griffiths and Gillies to produce hypotension the position of the patient and the effect of gravity must be of major importance, and it has been found that these factors are equally important when pentamethonium iodide is used.

Fig. 1 clearly demonstrates that gravitational pooling of blood in the legs is the important factor in the production of hypotension. This is supported by the work of Burt and Graham (1950), who showed that the greatest vasodilatation occurred in the legs. When vasomotor control has been abolished, placing the patient in the lateral or prone jack-knife position leads to a profound fall in blood-pressure (figs. 1 and 3). This applies to high spinal analgesia or to any drug which will effectively inhibit the vasomotor reflexes.

Since there are many operations in which neither of these positions is appropriate, a foot-down tilt of 15–20 has been used, which gives a moderate yet still valuable reduction in blood-pressure (fig. 2).

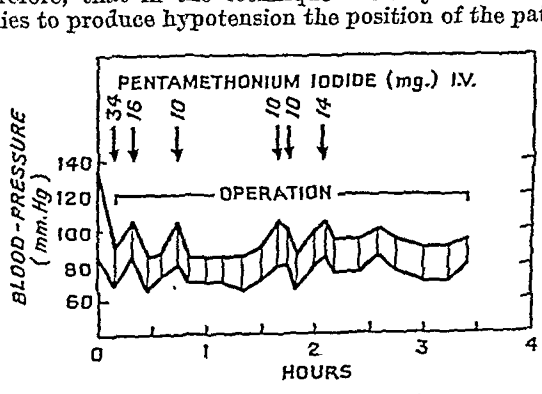

Fig. 2—Blood-pressure during spinal decompression in severe congenital kyphosis in male, aged 19, prone, with foot of operating-table tilted downwards 20°. Reduction of bleeding, owing to low blood-pressure, was of great assistance to surgeon. Blood-pressure before operation was 150/95 mm. Hg, and at end of operation, with patient supine and horizontal, 120/90 mm. Hg.

There is another group of patients whose blood-pressure falls sharply immediately after the drug is injected without the assistance of gravity. In their report on pentamethonium iodide Arnold and Rosenheim (1949 described a sharp fall of blood-pressure in hypertensive patients, and a similar and more extreme reaction is sometimes seen under anæsthesia, whether or not the patient is hypertensive. The first case encountered showed a pronounced fall after 30 mg. of pentamethonium iodide had been given intravenously.

More recently, with the necessary postural precautions, extreme hypotension has been continued satisfactorily for periods up to an hour (fig. 4). In these cases the patient's condition should be assessed during the hypotensive period on much the same lines as are indicated by Griffiths and Gillies (1948), particular attention being given to the state of the capillary circulation and to the pulse-rate, obtained if necessary from the apex-beat. In my cases it has so far always been possible to feel the pulse in either the carotid or the femoral artery, and a sensitive recording apparatus might have demonstrated a blood-pressure of about 30–60 mm. Hg. With this degree of hypotension the posture must be such that the cerebral circulation is helped by gravity; and it is always a comfort to have an injection of 'Methedrine' at hand for immediate use if desired. However, methedrine should not be given unless it is essential, and then only in a dose sufficient to restore a fraction of the blood-pressure; for a sudden rise will open vessels which otherwise would have become sealed effectively by contraction and thrombosis before being subjected again to normal pressures.

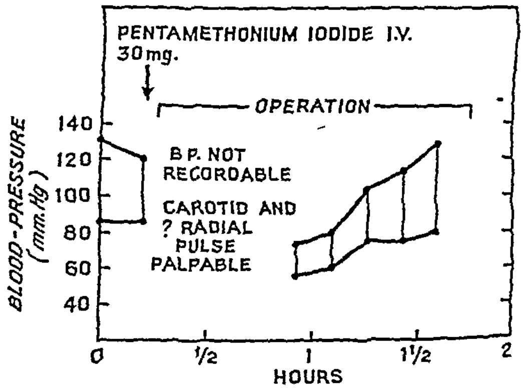

Fig. 3—Blood-pressure during lumbar sympathectomy in hypertensive arteriosclerotic male, aged 60, with patient in left lateral jack-knife position. Operation field was quite dry until blood-pressure rose towards end of operation. Blood-pressure before operation was 170/100 mm. Hg.

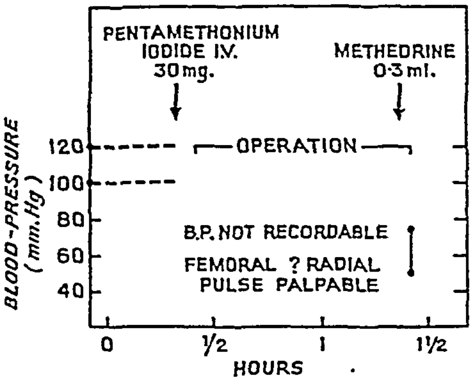
The total spinal technique is clearly contra-indicated in some conditions—e.g., severe spinal deformities—whereas with pentamethonium iodide it seems possible



ig. 4—Well-marked hypotension with minimal bleeding for an hour during excision of scar and insertion of tube pedicle in female, aged 21, in right lateral position for 20 minutes and then supine and 5° head down. Before operation blood-pressure was 135/85 mm. Hg. At end of operation blood-pressure was partly restored with methedrine.

o abolish vasomotor control easily and quickly in all ases, and further experience will probably lead to etter results, particularly in relation to the gravitational ffects of posture. Except in arteriosclerotic hyperensive patients, an effective reduction in blood-pressure s not usually attained without the assistance of gravity ; his probably has the effect of reducing the venous return o the heart, which in turn will diminish the cardiac utput and the blood-pressure. It is not sufficient nly to reduce the blood-pressure ; to prevent bleeding he patient must so be placed that the operation field s elevated and the blood can drain away from it.

There is an optimal dose of pentamethonium iodide which will paralyse the ganglia, and to exceed this serves no useful purpose apart perhaps from prolonging its action. I find that 30 mg. is reasonably adequate for all except the young healthy patient, but it is probably too much for arteriosclerotic hypertensives. In the latter I now start with 20 mg. and observe its effect before proceeding. Full effects appear in three minutes, while pressure changes due to gravity occur even quicker.

Pentamethonium iodide or other drugs of the series have been given in about fifty cases, but it is only in the most recent ones that the effects of posture have been fully appreciated. In twelve cases full use has been made of the effects of gravity. In those in which the blood-pressure was reduced to 80 mm. Hg there was a considerable diminution in bleeding, and in those showing more profound hypotension bleeding rapidly became insignificant.

A warning is necessary regarding cases which show only a moderate reduction to, say, 90–100 mm. Hg systolic. At this pressure bleeding will still occur, and if for any reason it is considerable and prolonged it is more dangerous than in the patient whose vasomotor system is under normal control. In such cases replacement therapy is essential.

Anæsthesia

Induction in all cases has been with thiopentone, usually followed by nitrous oxide and oxygen (2 : 1) in a closed-circuit absorber. Fractional doses of thiopentone are administered through a Gordh needle, which is also used for the pentamethonium iodide. It is always convenient to have immediate access to a vein ; but, if it should be necessary to use methedrine, the veins in the dependent parts are always well filled and present no difficulty. Of the other anæsthetic agents cyclopropane has not been used, because of its tendency to raise the blood-pressure. Trichlorethylene and ether have been used, but their influence, if any, has not yet been determined.

Under pentamethonium iodide the pupil is usually about three-quarters dilated and inactive to light, and the eyeball is fixed and central. The state of the pupil probably reflects the position of rest when both sympathetic and parasympathetic impulses have been inhibited. Recovery from this state seems to be slow, but so far there have been no postoperative complaints of interference with vision.

The immediate recovery from the anæsthetic is not delayed in any way, and the cough reflex quickly returns. The blood-pressure is usually restored to a low normal level on reversion to the horizontal position. The patients with the more extreme degrees of hypotension recover in about two hours, but their blood-pressure is often low for some hours later.

The patients' postoperative condition is particularly pleasing, and so far no ill effects whatever have been noted. Two patients said they were sleepy on the day after operation.

SUMMARY

In the past six months pentamethonium iodide, tetraethylammonium chloride, or hexamethonium iodide has been given to fifty anæsthetised patients to produce hypotension.

To lower the blood-pressure sufficiently to reduce bleeding at operation it is usually necessary to place the patient in a position that will allow the blood to gravitate into the dilated vessels. The greatest vasodilatation occurs in the legs, so their position is particularly important.

Where full use was made of the effects of gravity a valuable reduction in bleeding was obtained.

No ill effects were observed.

My thanks are due to Dr. J. Gillies and Dr. H. W. C. Griffiths for information and assistance, and to Mr. H. J. Seddon for his helpful advice and criticism. Messrs. Allen and Hanburys Ltd. supplied the pentamethonium iodide ('Antilusin').

ADDENDUM

In the ten weeks since this paper was completed more information has been obtained on the gravitational effects of posture with this drug. To obtain an effective reduction of blood-pressure it has at times been necessary to increase the foot-down tilt to 30°–40°, and to assist lesser degrees by dropping one or both legs over the side of the table with the patient supine.

Out of a total of 35 cases, excellent results have been obtained in 18, a moderate reduction in bleeding in 8, and no helpful effects in 9. Where there is no effect or but little reduction in bleeding this is because the blood-pressure has not been lowered sufficiently. This may be due to inadequate posture, for the more extreme positions are often incompatible with the surgery. There may also be constitutional differences between patients.

Bleeding is considerably reduced in all fields of surgery when the systolic pressure is between 60 and 70 mm. Hg, but in some regions it is possible to keep the systolic pressure at 70–80 or even over 80 mm. Hg and still obtain the required effect.

The problem as I see it still is to reduce the blood-pressure to 60 mm. Hg in all cases requiring it, for so often with pentamethonium iodide the reduction falls short of this by a small margin.

THE NERVOUS MANIFESTATIONS OF PERIARTERITIS NODOSA

V. K. SUMMERS
M.D. Lpool, M.R.C.P.
RESEARCH ASSISTANT, DEPARTMENT OF PATHOLOGY, UNIVERSITY OF LIVERPOOL

Periarteritis nodosa is a necrotising panarteritis, principally affecting blood-vessels of small or medium size. General symptoms (from the inflammatory reaction) and focal symptoms (from the disseminated arterial lesions) give it protean manifestations. The disease is not rare (Miller 1949) but its diagnosis can be difficult and it often goes unrecognised.

Although the primary lesions are scattered throughout the body, one particular part of the body is often more affected than the rest. In the three cases described here the brunt of the disease fell on the nervous system. Involvement of the intracerebral vessels is relatively uncommon, the reported frequency varying from 8% (Gruber 1926) to 20% (Foster and Malamud 1941).

CASE 1

This case illustrates the occurrence of spontaneous subarachnoid hæmorrhage and a vascular lesion affecting the right middle cerebral artery.

A man, aged 35, was admitted on Feb. 3, 1946, with a history of having had tonsillitis ten months earlier, accompanied by pains in the right knee and both ankle-joints. On the evening preceding his admission to hospital he had had severe occipital headache, and within four hours had become unconscious.

On admission he was comatose, with stertorous breathing and severe neck rigidity. Kernig's sign was positive. Both plantar responses were extensor. His blood-pressure was 160/100 mm. Hg and his urine contained albumin. Lumbar puncture produced a heavily bloodstained cerebrospinal fluid (C.S.F.). Spontaneous subarachnoid hæmorrhage due to rupture of a congenital aneurysm was diagnosed.

Progress.—The patient gradually recovered, but unexplained pyrexia persisted. There was a leucocytosis of 17,500 cells per c.mm. On the twenty-seventh day after his admission he had a sudden onset of left hemiplegia. His C.S.F. was under pressure and the protein was increased to 100 mg. per 100 ml.

At this stage the possibility of secondary cerebral deposits from an undiscovered primary neoplasm was considered. Despite careful search, no primary growth was discovered, though the impression of malignant disease was strengthened by the rapid deterioration in the patient's condition. He died on the thirty-seventh day after admission.

Necropsy made the diagnosis obvious. There was a leaking aneurysm on the left posterior cerebral artery, thrombosis of the right middle cerebral artery, and multiple hæmorrhagic nodules in both kidneys, liver, and spleen. Microscopically typical lesions of periarteritis nodosa were found in the heart, liver, spleen, brain, and kidneys.

The diagnosis was not suspected in life, though in retrospect there were several obvious pointers. The experimental studies of Rich (1942) and Rich and Gregory (1943) demonstrated that in rabbits a necrotising periarteritis could be produced by injecting foreign serum. The occurrence of periarteritis in close time relationship with various infections has often been noted; in particular, streptococcal infections have often preceded the onset of the disease (Manges and Baehr 1921, Dietrich 1933, Vining 1938). This patient had a history of rheumatism, probably an allergic reaction to streptococcal infection. Other facts which pointed to periarteritis were the persistent pyrexia, high leucocytosis, hypertension, and albuminuria.

CASE 2

This case, in which periarteritis was diagnosed during life, presented as a polyneuritis affecting chiefly the extensor muscles of both wrists.

A man, aged 54, was admitted on May 1, 1949. Two previously he had complained of pain in both calves weakness of both legs. His legs had been so weak that he had fallen to the ground, but he had not lost consciousness.

On examination he was thin and youthful-looking, with circular pupils that were equal and reacted normally. All his cranial nerves seemed to have normal function. All movements of his right arm were weaker than those of his left. The tendon reflexes in the arms were equal on both sides. Apart from tenderness of the calf muscles, there were no changes in the legs. Loss of pain sensation was noted on the right forearm and hand.

Progress.—Within five days of the patient's admission the extensors of his right wrist and the plantar flexors of his left foot became very weak. On June 2, 1949, severe epigastric pain came on; but, apart from muscle guarding in the epigastrium, no localising signs were present. Marked weakness of the extensors of the left wrist was noted, together with patchy impairment of sensation. Throughout the whole course of the illness a high pyrexia persisted. His white-cell count was 30,000 per c.mm. (polymorphs 90%). Blood-cultures were sterile. The blood Wassermann reaction was strongly positive but the C.S.F. Wassermann negative. The C.S.F. was normal in cytology and chemistry. The blood-pressure was 170/100 mm. Hg. He died seventeen weeks after admission.

Necropsy confirmed the clinical diagnosis of periarteritis nodosa. Typical lesions were found in the small intestine, pancreas, kidneys, and liver. Microscopy showed changes characteristic of periarteritis nodosa.

The symmetrical polyneuritis in the arms, pyrexia, leucocytosis, albuminuria, hypertension, and visceral pain pointed clearly to periarteritis nodosa. The positive serological reaction for syphilis is a noteworthy feature of this case; Chvostek and Weichselbaum (1877), Gruber (1926), and Volland (1936) have reported instances of periarteritis following syphilitic infection.

Kernohan and Woltman (1938) noted polyneuritis in association with periarteritis nodosa in 20% of cases. A higher incidence was recorded by Jones (1940), who found evidence of peripheral neuritis in 9 out of 14 cases. Careful neurological examination will probably show that polyneuritis is much more common than is suggested by Kernohan and Woltman. The pathological basis of the polyneuritis in periarteritis nodosa was demonstrated by Wohlwill (1923) to be an endarteritis of the vasa nervorum. It has been suggested by Baló (1926) and Kulkow (1941) that the polyneuritis of periarteritis nodosa is toxic, but Nelson (cited by Miller 1949) has demonstrated endarteritis of the vasa nervorum in many of these cases.

Miller (1949) proposes to classify the peripheral neuritis of periarteritis into three main forms: (1) a mononeuritis multiplex with asymmetrical neuritis of nerve-trunks; (2) a symmetrical polyneuritis, usually maximal in the lower limbs, together with a neuritis of individual nerve-trunks; and (3) symmetrical polyneuritis alone. The detailed systematisation of the symptoms of this necessarily pleomorphic disease is undesirable. Rather is it necessary to call attention to the bizarre distribution of the neuritis and to emphasise the consideration of periarteritis nodosa in the differential diagnosis of infective polyneuritis.

CASE 3

The last case in this series presented features which pointed to acute infective polyneuritis involving both the peripheral and the cranial nerves.

A woman, aged 21, attended the outpatient department in December, 1947. Six weeks earlier she had had a sore throat and stiff neck. This illness had responded well to sulphadiazine. On Dec. 18, 1947, she had had diplopia, and three days later difficulty in walking and paræsthesiæ in both hands.

On examination she had slight ptosis of the right eyelid, palsy of the right external rectus, immobility of the palate, patchy anæsthesia to light touch on the palms and anterior surfaces of the fingers of both hands, and absent vibration sense as far as the elbows of both arms.

Progress.—On Dec. 23, 1947, she had a complete right external ophthalmoplegia and absent vibration sense in the egs. Her C.S.F. was under increased pressure (300 mm. of water), the protein content was raised to 80 mg. per 100 ml., and there were 35 polymorphs per c.mm. Pyrexia persisted throughout the illness. The urine contained a moderate amount of albumin and a few red cells and granular casts. A blood-count showed red cells 3,500,000 per c.mm., Hb 65%, and white cells 15,500 per c.mm. (polymorphs 85%).

On the eighteenth day of illness the spleen became palpable and tender. Three days later there was a frank hæmaturia, and four days later blurring of vision in the left eye. Multiple elevations or detachments of the retina were noted, together with choroidal exudates.

From then onwards the patient went progressively downhill, and died on the thirtieth day after admission.

Necropsy revealed typical changes of periarteritis in the brain, meninges, kidneys, spleen, liver, and retina.

This case again illustrates the development of periarteritis nodosa in the wake of a streptococcal infection. The very widespread nature of the lesions of this disease are also well illustrated. The occurrence of changes in the retinal vessels in periarteritis nodosa was first noticed by Müller (1899), and many workers have noticed arteriosclerotic retinal changes. Sampson (1945) has described the typical retinal lesions of periarteritis nodosa as multiple retinal detachment, choroidal exudates, and, ultimately, typical arteriosclerotic changes in the vessels. Conjunctivitis and chemosis have also been described by Peron and Desvignes (1947).

DISCUSSION

Though nervous involvement is not one of the common manifestations of periarteritis nodosa these three cases, in which the main incidence was on the nervous system, show that the possibility of periarteritis nodosa should be kept in mind when bizarre clinical patterns of polyneuritis are encountered. Other signs can usually be found to establish the diagnosis. Pyrexia always occurs at some time in the course of the disease, and leucocytosis, albuminuria, hypertension, and splenomegaly are often found. Difficulty in diagnosis usually arises because the possibility of periarteritis nodosa is not considered.

SUMMARY

Three cases of periarteritis nodosa are described in which the chief presenting clinical signs were due to involvement of the nervous system.

The importance of considering this diagnosis in obscure cases of polyneuritis is emphasised, and the more important nervous manifestations of the syndrome are briefly reviewed.

A.C.T.H. IN RHEUMATOID ARTHRITIS
COMPARED WITH INTRAMUSCULAR ADRENALINE AND WITH DEOXYCORTONE AND ASCORBIC ACID

ELLIS DRESNER M.B. Durh.
L. G. C. PUGH M.A., B.M. Oxfd
J. B. WILD M.D. Lond., M.R.C.P.

From the Department of Medicine, Postgraduate Medical School of London

THE dramatic effects of the adrenocortical steroid hormone 'Cortisone' and of anterior pituitary adrenocorticotrophic hormone (A.C.T.H.) in alleviating the symptoms of rheumatoid arthritis (Hench et al. 1949) have been amply confirmed (Markson 1949, Elkinton et al. 1949). Attempts have been made to produce similar results by stimulation of the adrenal cortex with adrenaline (Thorn et al. 1949), and Godlowski (1949) has claimed benefit in some cases of rheumatoid arthritis treated with this drug. The claim of Lewin and Wassén (1949) that the simultaneous injection of deoxycortone acetate and ascorbic acid in rheumatoid arthritis produces a striking and even more rapid improvement than that of cortisone or A.C.T.H., has aroused considerable interest, and is strongly supported by Le Vay and Loxton (1949, 1950) and others. Some workers, however, have failed to demonstrate any objective or subjective change following the administration of these compounds (Kellgren 1949, Spies et al. 1949, Kersley et al. 1950, Currie and Will 1950, Bywaters et al. 1950).

In the following case of rheumatoid arthritis treated with A.C.T.H. the effects observed have been compared with those obtained in the same patient with adrenaline, and with deoxycortone acetate and ascorbic acid.

CASE-HISTORY

The patient, a printer aged 42, was admitted to hospital in September, 1949, suffering from rheumatoid arthritis of four years' duration. His previous health had been good, and there was nothing relevant in the family history. The illness began insidiously at the end of 1946 during a period of stress in connection with the reconstruction of his business, which had declined during his absence on military service. The first symptoms were migratory muscle pains and lassitude. In March, 1947, he was admitted to hospital with pain, swelling, and stiffness of the proximal finger-joints. His erythrocyte-sedimentation rate (E.S.R.) was 72 mm. in one hour (Westergren). Although the symptoms subsided with rest in bed, they recurred soon after discharge; and from May, 1947, the illness ran a progressive course with little remission. By June, 1947, his hands, feet, elbows, shoulders, knees, hips, cervical spine, and temporomandibular joints were involved; he was unable to walk, shave himself, brush his hair, or handle a knife. Biopsy of a subcutaneous nodule from the right ankle confirmed the diagnosis of rheumatoid arthritis. From August, 1948, to April, 1949, he received a course of weekly injections of gold (total 1·0 g. of 'Myocrisin') with little benefit. At the time of his present admission to hospital he had been bedridden for eighteen months. He was admitted under Dr. E. G. L. Bywaters on Sept. 19.

Findings on admission.—A coöperative, intelligent man, slightly overweight. The skin, throat, and nails were normal. He was edentulous. No abnormality was found in his lungs, abdomen, heart, or central nervous system. Blood-pressure 134/90 mm. Hg. Urine normal.

Joints.—Movements of the *cervical spine, temporomandibular joints, hips, and shoulders* were severely restricted by pain. There was a moderate degree of periarticular swelling of both *elbows* and 10° limitation of full extension. Both *wrists* were swollen, and movement at these joints was restricted to 10° palmar flexion on the right side and 20° on the left. The metacarpophalangeal and proximal interphalangeal joints of both *hands* were swollen and tender and his grips were weak. There were bilateral effusions into both *knee-joints*, the synovial membranes of which were palpably thickened. Movements of the *ankles* were restricted and both joints were swollen and painful.

THE NERVOUS MANIFESTATIONS OF PERIARTERITIS NODOSA

V. K. SUMMERS
M.D. Lpool, M.R.C.P.
RESEARCH ASSISTANT, DEPARTMENT OF PATHOLOGY, UNIVERSITY OF LIVERPOOL

Periarteritis nodosa is a necrotising panarteritis, principally affecting blood-vessels of small or medium size. General symptoms (from the inflammatory reaction) and focal symptoms (from the disseminated arterial lesions) give it protean manifestations. The disease is not rare (Miller 1949) but its diagnosis can be difficult and it often goes unrecognised.

Although the primary lesions are scattered throughout the body, one particular part of the body is often more affected than the rest. In the three cases described here the brunt of the disease fell on the nervous system. Involvement of the intracerebral vessels is relatively uncommon, the reported frequency varying from 8% (Gruber 1926) to 20% (Foster and Malamud 1941).

CASE 1

This case illustrates the occurrence of spontaneous subarachnoid hæmorrhage and a vascular lesion affecting the right middle cerebral artery.

A man, aged 35, was admitted on Feb. 3, 1946, with a history of having had tonsillitis ten months earlier, accompanied by pains in the right knee and both ankle-joints. On the evening preceding his admission to hospital he had had severe occipital headache, and within four hours had become unconscious.

On admission he was comatose, with stertorous breathing and severe neck rigidity. Kernig's sign was positive. Both plantar responses were extensor. His blood-pressure was 160/100 mm. Hg and his urine contained albumin. Lumbar puncture produced a heavily bloodstained cerebrospinal fluid (C.S.F.). Spontaneous subarachnoid hæmorrhage due to rupture of a congenital aneurysm was diagnosed.

Progress.—The patient gradually recovered, but unexplained pyrexia persisted. There was a leucocytosis of 17,500 cells per c.mm. On the twenty-seventh day after his admission he had a sudden onset of left hemiplegia. His C.S.F. was under pressure and the protein was increased to 100 mg. per 100 ml.

At this stage the possibility of secondary cerebral deposits from an undiscovered primary neoplasm was considered. Despite careful search, no primary growth was discovered, though the impression of malignant disease was strengthened by the rapid deterioration in the patient's condition. He died on the thirty-seventh day after admission.

Necropsy made the diagnosis obvious. There was a leaking aneurysm on the left posterior cerebral artery, thrombosis of the right middle cerebral artery, and multiple hæmorrhagic nodules in both kidneys, liver, and spleen. Microscopically typical lesions of periarteritis nodosa were found in the heart, liver, spleen, brain, and kidneys.

The diagnosis was not suspected in life, though in retrospect there were several obvious pointers. The experimental studies of Rich (1942) and Rich and Gregory (1943) demonstrated that in rabbits a necrotising periarteritis could be produced by injecting foreign serum. The occurrence of periarteritis in close time relationship with various infections has often been noted; in particular, streptococcal infections have often preceded the onset of the disease (Manges and Baehr 1921, Dietrich 1933, Vining 1938). This patient had a history of rheumatism, probably an allergic reaction to streptococcal infection. Other facts which pointed to periarteritis were the persistent pyrexia, high leucocytosis, hypertension, and albuminuria.

CASE 2

This case, in which periarteritis was diagnosed during life, presented as a polyneuritis affecting chiefly the extensor muscles of both wrists.

A man, aged 54, was admitted on May 1, 1949. Two previously he had complained of pain in both calves weakness of both legs. His legs had been so weak that he had fallen to the ground, but he had not lost consciousness.

On examination he was thin and youthful-looking, with circular pupils that were equal and reacted normally. All his cranial nerves seemed to have normal function. All movements of his right arm were weaker than those of his left. The tendon reflexes in the arms were equal on both sides. Apart from tenderness of the calf muscles, there were no changes in the legs. Loss of pain sensation was noted on the right forearm and hand.

Progress.—Within five days of the patient's admission the extensors of his right wrist and the plantar flexors of his left foot became very weak. On June 2, 1949, severe epigastric pain came on; but, apart from muscle guarding in the epigastrium, no localising signs were present. Marked weakness of the extensors of the left wrist was noted, together with patchy impairment of sensation. Throughout the whole course of the illness a high pyrexia persisted. His white-cell count was 30,000 per c.mm. (polymorphs 90%). Blood-cultures were sterile. The blood Wassermann reaction was strongly positive but the C.S.F. Wassermann negative. The C.S.F. was normal in cytology and chemistry. The blood-pressure was 170/100 mm. Hg. He died seventeen weeks after admission.

Necropsy confirmed the clinical diagnosis of periarteritis nodosa. Typical lesions were found in the small intestine, pancreas, kidneys, and liver. Microscopy showed changes characteristic of periarteritis nodosa.

The symmetrical polyneuritis in the arms, pyrexia, leucocytosis, albuminuria, hypertension, and visceral pain pointed clearly to periarteritis nodosa. The positive serological reaction for syphilis is a noteworthy feature of this case; Chvostek and Weichselbaum (1877), Gruber (1926), and Volland (1936) have reported instances of periarteritis following syphilitic infection.

Kernohan and Woltman (1938) noted polyneuritis in association with periarteritis nodosa in 20% of cases. A higher incidence was recorded by Jones (1940), who found evidence of peripheral neuritis in 9 out of 14 cases. Careful neurological examination will probably show that polyneuritis is much more common than is suggested by Kernohan and Woltman. The pathological basis of the polyneuritis in periarteritis nodosa was demonstrated by Wohlwill (1923) to be an endarteritis of the vasa nervorum. It has been suggested by Baló (1926) and Kulkow (1941) that the polyneuritis of periarteritis nodosa is toxic, but Nelson (cited by Miller 1949) has demonstrated endarteritis of the vasa nervorum in many of these cases.

Miller (1949) proposes to classify the peripheral neuritis of periarteritis into three main forms: (1) a mononeuritis multiplex with asymmetrical neuritis of nerve-trunks; (2) a symmetrical polyneuritis, usually maximal in the lower limbs, together with a neuritis of individual nerve-trunks; and (3) symmetrical polyneuritis alone. The detailed systematisation of the symptoms of this necessarily pleomorphic disease is undesirable. Rather is it necessary to call attention to the bizarre distribution of the neuritis and to emphasise the consideration of periarteritis nodosa in the differential diagnosis of infective polyneuritis.

CASE 3

The last case in this series presented features which pointed to acute infective polyneuritis involving both the peripheral and the cranial nerves.

A woman, aged 21, attended the outpatient department in December, 1947. Six weeks earlier she had had a sore throat and stiff neck. This illness had responded well to sulphadiazine. On Dec. 18, 1947, she had had diplopia, and three days later difficulty in walking and paræsthesiæ in both hands.

with great difficulty, and was unable to get out of bed or walk, even with assistance.

In spite of the striking clinical improvement, objective measurements of joint function by the methods used showed relatively small changes (fig. 1). There was little increase in the range of joint movements, but within their range the movements became free and painless. The E.S.R. fell during A.C.T.H. therapy from 120 to 22 mm. On the 5th day after treatment it had risen once more to 70 mm. (fig. 2).

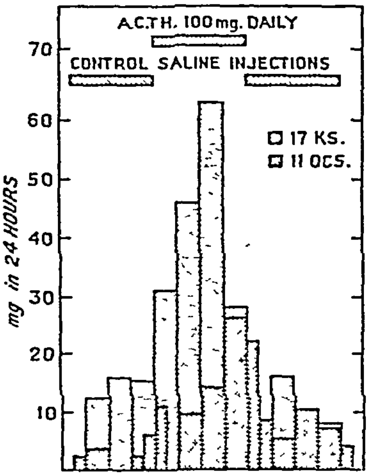

Fig. 3—Effects of A.C.T.H. on urinary excretion of 17-ketosteroids (stippled columns) and 11-oxysteroids (hatched columns).

After discontinuation of A.C.T.H. the patient gradually relapsed. He complained of pain in the neck and left hip 5 hours after the final injection, but did not require to take analgesic tablets until 8 days later. By the end of a month, his clinical condition as regards joint pains and stiffness was comparable with his state before the administration of A.C.T.H.

Hæmatological effects (fig. 2).—Circulating eosinophils had disappeared from the blood 4 hours after the first A.C.T.H. injection and none were found in daily counts during the whole period of treatment. They reappeared within a few hours of discontinuing A.C.T.H. A marked rise in total white blood-cells to 21,000 per c.mm. during the period of therapy was due to an increase in polymorphonuclear leucocytes, the lymphocytes remaining at a fairly constant level. There was no significant change in red-cell counts, hæmoglobin levels, or hæmatocrit readings, or in the serum thymol-turbidity or colloidal-gold flocculation tests.

Blood-pressure.—Average readings of systolic blood-pressure rose from 134–144 mm. Hg during the control periods to 145–152 mm. during therapy. Diastolic readings were unaffected.

Metabolic effects.—The nitrogen balance was negative during A.C.T.H. therapy. Serum uric-acid values fell from an average level of 5·8 mg. per 100 ml. during the first control period to an average level of 2·6 mg. from the 3rd to the 9th day of treatment. Minor changes only were noted in the serum electrolytes, with the exception of potassium, which fell from 20 mg. per 100 ml. before treatment to 15 mg. on the 8th day of treatment. The electrocardiogram showed a fall in voltage of the T waves consistent with a low serum-potassium. The fasting blood-sugar levels did not change significantly on A.C.T.H. and there was no significant alteration in basal metabolic rate.

Excretion of steroid hormones (fig. 3).—There was an increase in the urinary excretion of 17-ketosteroids and 11-oxysteroids during A.C.T.H. administration and a rapid return to control levels at the end of treatment.

Adrenaline

By the time the adrenaline trial began, the patient had relapsed completely and his clinical state was comparable to that before A.C.T.H. All the affected joints were painful and restricted and many were swollen. Morning stiffness was severe. The patient was completely bedridden, and unable to handle a knife and fork, get out of bed, or wash himself. He required 8 analgesic tablets daily.

Administration of adrenaline in oil, 2·0 mg. daily for 14 days, produced no subjective clinical improvement, and objective measurements of joint function, as described for the A.C.T.H. trial, showed no significant deviation from the control periods. His daily requirement of analgesic tablets remained unaltered. The E.S.R., which varied from 72–77 mm. during the first control period, showed a tendency to fall when adrenaline was given, and 7 days afterwards had fallen to 50 mm.

Hæmatological effects (fig. 4).—There was little change in the total white-cell count, and lymphocytes remained fairly constant. The eosinophils fell to 50% of the resting level during the first 24 hours on adrenaline, but after 48 hours had risen again to the resting level, and thereafter rose steadily, reaching a maximum 4 days after adrenaline was stopped. Red-cell counts, hæmoglobin levels, hæmatocrit readings, and serum flocculation tests showed no appreciable change.

Blood-pressure.—There was a moderate rise in systolic blood-pressure, and a lesser rise in diastolic pressure, during the first two days on adrenaline.

Metabolic effects.—The fasting blood-sugar level rose immediately after adrenaline was started and remained elevated during the period of its administration, thereafter falling to normal. The maximum reading (167 mg.) was on the first day of therapy. Glycosuria did not develop.

There was no significant alteration in the body electrolytes.

Steroid hormones.—The excretion of 17-ketosteroids remained within normal limits during the whole of the adrenaline trial, and there was no increase during the test period. The urinary oxysteroids rose towards the end of adrenaline administration to a maximum of 10 mg. per day, the range of excretion during the control periods being 2–6 mg. in 24 hours.

Deoxycortone and Ascorbic Acid

Deoxycortone acetate 5 mg., and ascorbic acid 1 g., were given by intramuscular injection thrice daily for

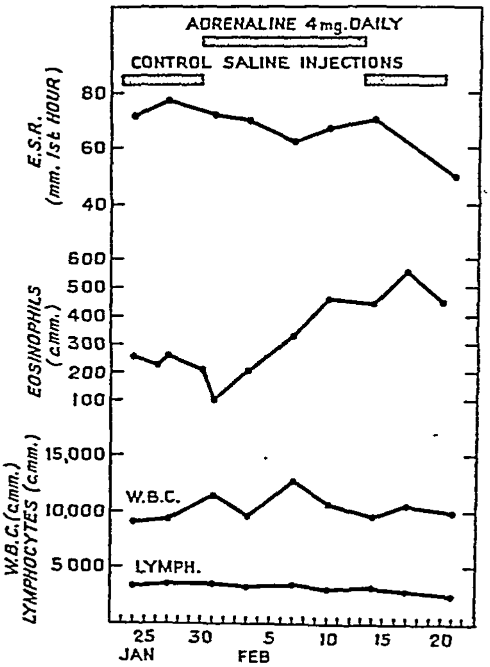

Fig. 4—Hæmatological effects of adrenaline.

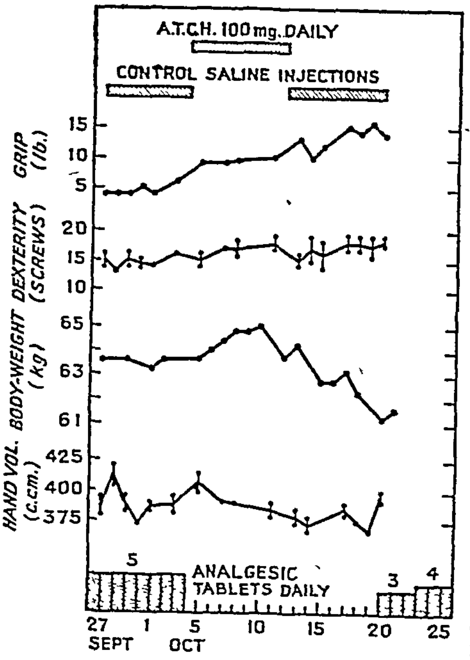

Fig. 1—Clinical effects of A.C.T.H. In spite of complete relief of pain, objective measurement of hand volume, dexterity, and grip show no significant changes. Note the gain in weight attributable to water retention.

Laboratory investigations.—The E.S.R. was 77 mm. in the first hour. The hæmoglobin was 12·7 g. per 100 ml. and red-cell count 4·0 million per c.mm. The white-cell count was 9500 per c.mm. (polymorphs 67%, eosinophils 1%, lymphocytes 30%, monocytes 2%). The serum uric acid and cholesterol and the plasma proteins were within normal limits.

Radiographs of the affected joints were characteristic of established rheumatoid arthritis. The bones were generally decalcified, there were subchondral erosions in the finger-joints, and the joint spaces were reduced.

METHODS OF STUDY

The patient was kept under clinical observation for one week before the investigations started. During the A.C.T.H. and adrenaline trials he was maintained on a constant food and water intake.

The A.C.T.H. trial began on Sept. 27 and lasted 25 days. For 9 days 100 mg. of A.C.T.H. was given daily by the intramuscular injection of 25 mg.* at 7 A.M., 12, and 5, and 10 P.M. The first and last 8 days served as control periods during which intramuscular injections of sterile saline solution were given. In this and the subsequent treatments, the nature of the injections was unknown to the patient or nursing staff.

The trial of adrenaline began on Jan. 23, 1950, and lasted 28 days. During the first and fourth weeks control injections of saline were given 6-hourly. During the middle 14-day period 0·5 mg. of adrenaline in oil was given 6-hourly.

During the first control week of this trial a preliminary injection of 0·3 mg. adrenaline was given to ascertain the eosinophil response. The result was a fall of the circulating eosinophils to 52% of the resting level at the 4th hour, indicating that the adrenal cortex was capable of responding to adrenaline stimulation.

Deoxycortone and ascorbic acid were given for 4 days from Feb. 25 to 28 inclusive, with control periods of 4 days on saline injections before and afterwards. The drugs were given by simultaneous intramuscular injections of 5 mg. of deoxycortone acetate and 1 g. of ascorbic acid thrice daily. During this trial, clinical assessments and hæmatological investigations were carried out daily, but no metabolic investigations were done.

Clinical assessment.—A cinematograph record was made before and during A.C.T.H. therapy. Day-to-day progress was assessed by the following methods, the measurements being made at the same time each day. Passive movement of all affected joints was measured with a goniometer, strength of grip with a spring dynamometer, and manual dexterity by means of a screw-plate test. This test consists in screwing nuts on to rows of bolts projecting vertically from a base plate. The test score is the number of nuts screwed on in 2 minut The score for a normal individual is 27–30.

Changes in hand volume were followed by the method water displacement, the hand being immersed up to indelible mark drawn round the wrist. Measurements we made daily in duplicate.

An attempt was made to assess the symptomatic rel obtained with A.C.T.H. and other forms of therapy, by charti the number of analgesic tablets (tab. codein. co. *B.* required daily. A supply of these tablets was kept at t bedside.

Technical Methods

Eosinophil-counts were performed by the method Randolph (1944). Estimations of urinary 11-oxysteroids we carried out by Dr. C. L. Cope (method to be publishe Estimations of urinary 17-ketosteroids were carried out Dr. W. Klyne by a modification of the method of Call et al. (1938).

RESULTS

A.C.T.H.

Clinical effects.—During the first control period of t A.C.T.H. trial minor symptomatic fluctuations were not by the patient, but there was no sustained subjecti or objective improvement apart from a slight decrease tenderness and increase in mobility of the fingers. The was no corresponding increase in manual dexterity *significant alteration in the hand volume.* The E.S. remained high and eosinophils ranged from 120 to 24 per c.mm. of blood.

Within 5 hours of the first injection of A.C.T.H. th patient volunteered the information that his joints wer painless for the first time for over a year, relief beginnin 2 hours after the injection. His comment was: "tha last injection had a kick in it. I feel revitalised." Fo the next 16 days he required no analgesic tablets an slept without sedatives. His mental outlook becam cheerful an optimistic. Al movements be came quicke and mor forceful, an he was abl to wash, and brush his hai for the first time for 14 months. The hands and wrists were no longer tende on pressure and passive movements were painless. By the 4th day of A.C.T.H. therapy he was able to turn back the bedclothes, get out of bed, and walk a few steps without assistance. This was perhaps the most striking functional improvement, for previously he could turn back the bedclothes only

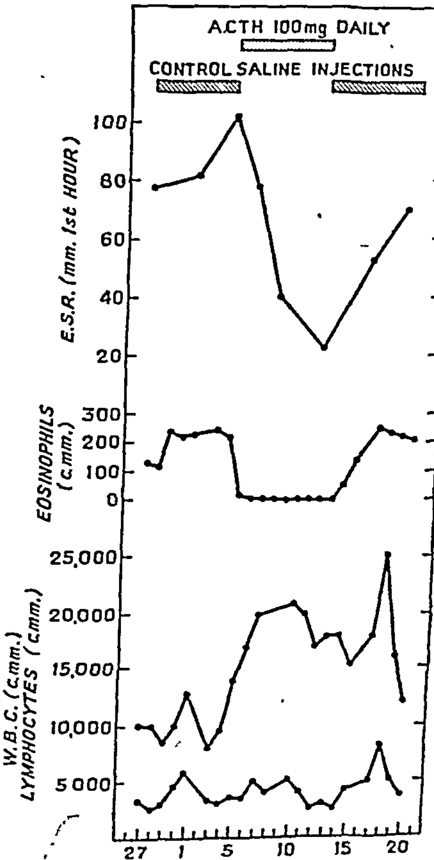

Fig. 2—Hæmatological effects of A.C.T.H.

---

* We are indebted to Messrs. Organon Laboratories for the A.C.T.H. used in this trial.

5. No clinical or other effects followed the administion of deoxycortone and ascorbic acid.

Ve are indebted to Dr. E. G. L. Bywaters for permission to lish this case, to Dr. W. Klyne for the urinary ketosteroid mations, to Dr. C. L. Cope for the estimations of reducing oids, and to Prof. E. J. King and his department for the aining biochemical estimations.

STEROID THERAPY IN RHEUMATOID ARTHRITIS

A FURTHER REPORT

G. D. KERSLEY M.D. Camb., F.R.C.P.
L. MANDEL M.B. Lpool, M.R.C.P.

m the South West and Oxford Regional Rheumatism Research nit, Royal National Hospital for Rheumatic Diseases, Bath

N April we reported a screening of certain steroids—inyl œstradiol, methyl testosterone, testosterone pionate, progesterone, and 'Pregnyl'—for their lue in rheumatoid arthritis, both alone and in combinan with ascorbic acid and at the same time comparing e effects with those of deoxycortone acetate and ascorbic id. Although there were a few fairly definite improveents throughout the series, we considered that their erapeutic value was not proved (Kersley et al. 1950).

Nevertheless, we felt that there were certain additional ints which required further investigation—namely, hether some other substance would take the place of corbic acid in an oxidase-reductase system and so oduce a more favourable result, and whether the use a steroid together with several injections of such a mpound (which is in any case very rapidly excreted) uld be beneficial and in that case whether a larger se of deoxycortone acetate would be advantageous.

As in our last series no change had been observed the eosinophil counts, urinary uric-acid/creatinine tios, and other laboratory tests, in this series clinical sessments only were made. This included observations changes in pain, stiffness, swelling, range of movement, d deep hyperalgesia, in addition to functional ability.

As a substitute for ascorbic acid, we decided to try oflavine, which is widespread in the body tissues and ich in combination with phosphoric acid is an portant co-enzyme with many dehydrogenases. Eleven ses were divided into three groups and each treated r three weeks with 2 injections per week of (A) prosterone and riboflavine, (B) progesterone and ascorbic id, and (C) saline as a control. Progesterone was used, a dose of 100 mg., because in our previous work this eroid had given as good a result as any of those tried. iboflavine 30 mg. was given intramuscularly or ascorbic id 1 g. was injected intravenously. In series A rogesterone and riboflavine) one patient was markedly tter, two slightly better, and one unaffected. In ries B (progesterone and ascorbic acid) one was markedly improved, one slightly improved, and two unaffected. In series C (saline) one was slightly improved at the end of the three weeks. It was considered that there was no significant clinical difference between the results of treatment with progesterone and riboflavine and with progesterone and ascorbic acid.

Another five patients were each given two injections of progesterone and riboflavine, followed a week later by deoxycortone acetate and riboflavine, and in a third week by saline as a control. All these injections were given on two successive days. Again there was no significant difference between the results of each series.

Six patients were given (*a*) saline, (*b*) the usual dosage of deoxycortone acetate 5 mg. and ascorbic acid 1 g., (*c*) deoxycortone acetate 5 mg. and three injections of ascorbic acid 1 g. at four-hourly intervals, and (*d*) deoxycortone acetate 25 mg. and three injections of ascorbic acid as above. No significant change was observed in the results of any of these series.

In four other cases we made an experiment which was exactly similar except that deoxycortone, and riboflavine were used instead of deoxycortone and ascorbic acid. Similar negative results were obtained.

SUMMARY AND CONCLUSIONS

1. Administration of progesterone with riboflavine 30 mg. did not produce a more favourable clinical result than the use of progesterone with ascorbic acid 1 g. It is doubtful whether their superiority over the use of saline is significant.
2. The clinical effect of progesterone and riboflavine was similar to that of deoxycortone acetate and riboflavine.
3. Three injections of ascorbic acid or riboflavine 4-hourly after the injection of deoxycortone acetate had no significant advantage over the single injection.
4. The use of deoxycortone acetate 25 mg., together with three injections of ascorbic acid or riboflavine, again appeared to have no enhancing therapeutic value.

ACCORDING to the many accounts of kernicterus or nuclear jaundice, this condition is usually associated with hæmolytic disease of the newborn. In the early report by Schmörl (1904), who first gave the name kernicterus to nuclear jaundice, the cases were typical of icterus gravis neonatorum, and Wiener and Brody (1946) state that kernicterus is found only in infants of mothers with agglutinating antibodies in their blood. No description can be found of the association of kernicterus with jaundice due to biliary obstruction without hæmolytic disease of the newborn, but various workers have suggested that neonatal sepsis together with hæmolytic disease may play some part in the development of kernicterus (de Bruyne and van Creveld 1948). Claireaux (1950) has lately declared that kernicterus is always associated with icterus gravis, arising from hæmolytic disease of the newborn; and Blackwood (1949) agrees with this view.

Claireaux suggests that the cells of the nuclear masses, and particularly the cornu ammonis, basal ganglia, inferior olives, and dentate nuclei, are severely affected by

4 days. No subjective or objective change was noted resulting from the administration of these drugs as compared with the control periods. Pains, swelling, and stiffness of joints were unaltered, and there was no decrease in the daily requirements of analgesic tablets.

The E.S.R. rose from 46 mm. before treatment to 90 mm. during the test period. Blood eosinophils fluctuated during the trial but there was no decrease as compared with the control periods. Other hæmatological findings remained unaltered (fig. 5).

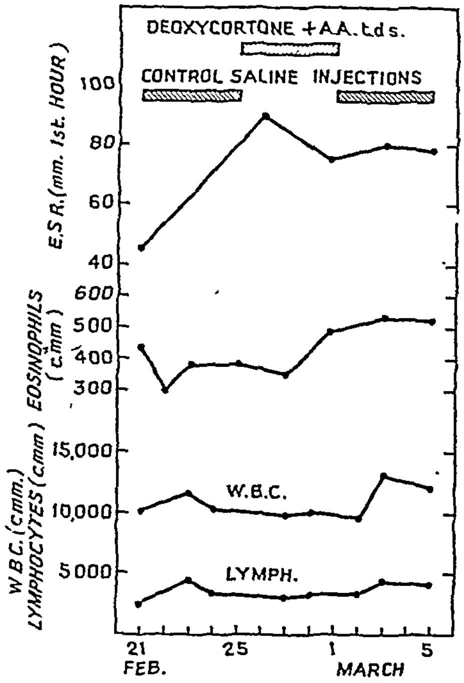

Fig. 5—Hæmatological effects of deoxycortone and ascorbic acid.

DISCUSSION

The remission induced by A.C.T.H. in this case was comparable to those originally obtained by Hench and his colleagues (1949) with cortisone and A.C.T.H. and to the results since obtained with A.C.T.H. by other workers (Markson 1949, Elkinton et al. 1949, Ragan et al. 1949, Thorn et al. 1949). A pronounced reduction in joint pains, tenderness, and stiffness, together with an increase in the speed, strength, and agility of movement, commenced within a few hours of the administration of A.C.T.H. and was sustained as long as the drug was given. Relapse followed withdrawal of the drug and was complete in about one month.

Evidence of stimulation of the adrenal cortex by A.C.T.H. was provided by a sustained fall in eosinophils, and increased excretion of 17-ketosteroids and 11-oxysteroids. No unpleasant side-effects occurred. The sense of physical and mental well-being which follows the abolition of the "toxic" feelings of rheumatoid arthritis by A.C.T.H. and cortisone was a prominent feature in this case.

In assessing the clinical remission induced by A.C.T.H., difficulty was encountered in selecting suitable measurements to demonstrate functional improvement. The tests used failed to express the over-all improvement in performance, as shown by the patient's ability to carry out tasks previously impossible for him; and, taken alone, they are misleading as a record of progress. The cinematograph film was the best record of this improvement, which might also have been assessed by noting the improvement in day-to-day measurements of the time taken to perform familiar and accustomed movements, such as tying a tie or writing a test sentence. It seems likely that improvement in performance of individual joints may be due to a reduction in pain, stiffness, and muscle spasm, leading to increased ability and willingness to use the joints, without necessarily any increase in their range or power.

Apart from the administration of cortisone and A.C.T.H., the level of cortical steroids in the body can be increased by the administration of adrenaline. This has been demonstrated in normal, but not in hypophysectomised, animals (Vogt 1944, Long 1947), indicating that the drug acts via the anterior pituitary and not by direct stimulation of the adrenal cortex. The most useful index of increased adrenocortical activity is a fall in the level of circulating eosinophils, caused by the 11, 17-oxysteroids (Compounds E and F). It has long been known that adrenaline can cause a temporary eosinopenia in man. Thorn et al. (1949), investigating the effects of adrenaline in cases of rheumatoid arthritis, confirmed this, and demonstrated an associated rise in the urinary excretion of 17-ketosteroids. These workers claimed a slight but definite clinical improvement in cases of rheumatoid arthritis treated with 1·2 to 2·0 mg. adrenaline daily, given intramuscularly for 2–4 weeks. Beneficial results in rheumatoid arthritis have also been claimed by Godlowski (1949) with adrenaline given intramuscularly or by intravenous infusion.

In the present study no subjective or objective clinical improvement resulted from the administration of 2·0 mg. adrenaline daily for 14 days, though there was a slight fall in the E.S.R. The eosinophils, which showed a 50% fall at the start of treatment, returned to the resting level within 48 hours and thereafter remained high. Urinary excretion of 17-ketosteroids was unchanged. The corticoids in the urine, which were low during the first period, showed a rise during treatment and then fell again when the drug was stopped. This increase occurred during the second week on adrenaline, when the eosinophil-count had risen to a high level. There were no demonstrable effects on serum or urinary electrolytes, and no other metabolic changes were seen. The usual clinical effects of adrenaline administration—apprehension, tremor, and palpitation—occurred after each injection. The data suggest that the adrenal cortex is stimulated less by adrenaline than by A.C.T.H.

The striking improvement claimed by Lewin and Wassén (1949) and Le Vay and Loxton (1949, 1950) from the use of deoxycortone and ascorbic acid in rheumatoid arthritis has been disputed by numerous authors (cited fully by Bywaters et al. 1950). In the present case, as in others we have studied, no demonstrable clinical or hæmatological effects followed the administration of deoxycortone and ascorbic acid for 4 consecutive days in the amounts recommended. The failure to elicit an eosinophil response with deoxycortone and ascorbic acid is in accord with the findings of others (Blackburn and Burke 1950).

In conclusion, it is of interest to record the patient's opinion of the therapeutic value of the three forms of treatment. On adrenaline and combined deoxycortone and ascorbic acid, though he showed initial enthusiasm, especially in the pre-treatment control periods, his final comment was: "They are not a patch on A.C.T.H."

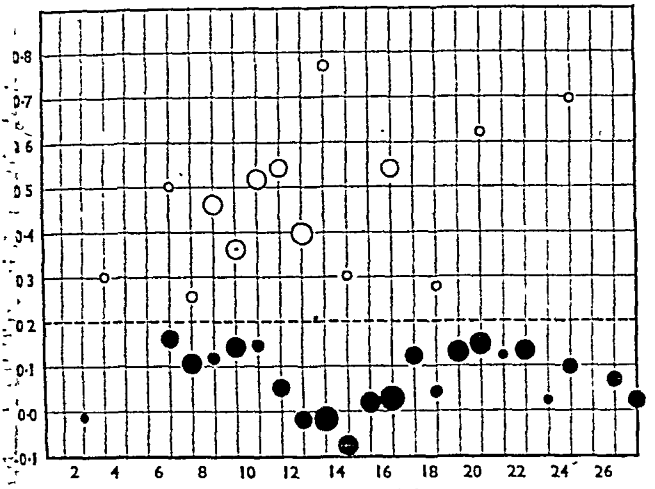
SUMMARY

1. The clinical and metabolic effects of A.C.T.H. have been studied in a case of severe rheumatoid arthritis treated with 100 mg. of the drug daily for 9 days.

2. No clinical improvement or significant changes were observed when the same patient was subsequently treated with adrenaline parenterally for 14 days, or during the 4 days when he also received deoxycortone and ascorbic acid by simultaneous injection thrice daily.

3. Adrenocortical stimulation by A.C.T.H. was shown by a sustained fall in circulating eosinophils and a rise in the urinary excretion of 17-ketosteroids and 11-oxysteroids.

4. Stimulation of the adrenal cortex by adrenaline was less marked than stimulation by A.C.T.H.



Average consistence of cervical secretions at different stages of menstrual cycle or of pregnancy in 86 non-pregnant women (black circles) and 35 pregnant women (open circles). Areas of circles are proportional to the number of cases included in the average, the smallest circle representing one case.

being sufficient. In its present form, however, the instrument is still in the experimental stage and not yet by any means perfect.

The records obtained are plots of the variations of pressure with length of column of material in the capillary tube. For a newtonian fluid these are straight lines, and although cervical secretions are very far from being true fluids they give plots which are virtually also straight lines. On the other hand, the direction of these lines clearly reveals the extent of the anomalous flow. In the present preliminary work two parameters are taken from the records: (1) the slope, and (2) the pressure of extrusion when the capillary tube is half full. The pressure is a measure of the over-all consistence. This is not readily correlated with the physiological state and has therefore been little used in the present work. The slope is certainly more useful. For most secretions, pressures fall as the tube empties, as would be expected, but at some stages of the sexual cycle secretions are found which actually require an increasing pressure as the fluid column shortens. In other words, their consistence increases considerably with shearing. Thus the slopes may be positive or negative. So that these values can be handled more conveniently they are all given the same sign by a suitable rotation of axes.

A programme of research has been carried out on human cervical secretions in which it was the intention to plot the slope against the date in the menstrual cycle for women in normal physical condition. The ideal way would have been to examine a few women daily throughout their cycles, as two of us (F. A. G. and G. W. S. B.) are doing in a similar programme on bovine secretions. It was not practicable to collect human samples so frequently, so instead samples were taken from a large number of women on one or two occasions. We were then confronted with the difficulty of the different lengths of their menstrual cycles. The length of cycle chosen for plotting was 27 days, this being the modal value.[5] The duration of the first part—from menstruation to ovulation—varies widely, whereas the second—from ovulation to the next menstruation—is relatively constant at 14–15 days.[6 7] Hence the dates for all patients examined within 14 days of the approaching menstruation were plotted as so many days before that event, whereas for those examined more than 14 days before menstruation the dates were plotted as a proportion of the interval before the 14th day. Thus we fitted each individual cycle length to the normal (a method similar to Palmer's [8]).

It was realised that this treatment could be criticised from the statistical point of view; but, considering that the preovulatory and postovulatory stages in the menstrual cycle consist of two entirely different processes, we thought this the best way of dealing with our problem.

Secretions were taken from 300 women attending the gynæcological and antenatal departments of a large hospital. Of these, 86 non-pregnant and 35 pregnant women were selected as being in normal physical condition. To confirm the occurrence of ovulation, endometrial biopsies were done, and in some cases basal temperature charts were also kept to ascertain the probable date of ovulation. Each patient was asked to state the date of the start of her previous menstruation, and later to notify the onset of the next period. We thus knew the date and length of the cycle in which the secretion was taken.

The average value of the slopes for all patients at the same adjusted date in the cycle was plotted against that date. There appeared to be one maximum at about the 8th day, another at about the 20th, and a minimum at the 14th. To justify postulating the existence of these maxima and minima, an analysis of variance was carried out on averages taken over every three days, and it was established that the differences between those averages were significant well beyond Fisher's $P = 0{\cdot}001$ level.

Two important points which do not appear in the figure must be noted. First, though the averages show non-pregnant and pregnant women clearly separated, there is an overlapping in the case of 3 women. These pregnancies were diagnosed by the clinician, but they have not yet reached the time of parturition. Some pregnant women who have given secretions of lower slopes than those expected have later been known to abort. Secondly, among the non-pregnant women, there is a very large scatter. Some of this spread is due to the physically heterogeneous nature of the samples, the very wide range of consistence encountered, and the errors introduced by the instrument and the operator.

So complicated is the physical state of these secretions that very little is known of their rheology. Our approach as yet has been largely empirical. The results are regarded as preliminary and encouraging for further work with an improved instrument which is already under construction.

It is known that the changes in the physical properties of these secretions are governed by the hormones acting on the cervical glands. Hence the measurements of these properties may well be correlated with hormone levels and perhaps serve as some estimate of them. Such a quick and convenient method of assay would be invaluable. We are therefore planning a series of experiments to test this hypothesis.

A more detailed account of our work is now in preparation.

One of us (F. A. G.) is indebted to the Agricultural Research Council for a grant enabling him to carry out this work.

anoxia (resulting from severe anæmia), which increases the cell permeability to bilirubin and gives rise to the typical yellow or orange staining; but the damage may not be severe enough to cause cell death, and in fact, Claireaux found that in infants dying within the first few days after birth, antemortem cell death was not present histologically. The only recent report on kernicterus without serological evidence of hæmolytic disease is that by Parsons (1947), who mentions two such cases.

RESULTS

In our experience, hæmolytic disease of the newborn is not the only, or the commonest, cause of kernicterus. Since 1948, post-mortem examinations have been made on altogether 239 infants dying in Southmead Hospital during the neonatal period. Of this total, 144 were premature.

In this series there were 14 proved cases of hæmolytic disease of the newborn, of which 10 showed kernicterus. There were 24 premature babies (i.e., infants weighing 5 lb. 8 oz. or less at birth) and one infant weighing 6 lb. 5 oz., in whom no evidence of hæmolytic disease could be found but all of whom showed typical kernicterus.

In these 25 cases the appearance of the brain macroscopically was indistinguishable from that in kernicterus due to hæmolytic disease. The intensity of the staining varied from pale lemon-yellow to deep orange. The distribution was variable, as it is in kernicterus associated with hæmolytic disease. In every case the cornu ammonis and the subthalamic nucleus showed staining, and in many cases there was also staining of the nuclei in the thalamus, midbrain, and medulla; often the floor of the 4th ventricle was stained. In no case was there biliary obstruction, nor was there any clinical or histological evidence of sepsis.

In 10 cases no other abnormality was found post-mortem. Of the remainder, 1 had a tentorial tear with slight hæmorrhage; 1 had hæmorrhagic disease of the newborn with melæna, which had ceased several days before death; and the others showed patchy areas of atelectasis in the lungs, with small intrapulmonary hæmorrhages in a few cases, and pulmonary œdema in 1 case only. In none of these cases was there histological evidence of lung infection.

In none of the 25 infants who died with kernicterus did the serological findings accord with a diagnosis of hæmolytic disease. The direct anti-human-globulin (Coombs) test, performed on the blood of the majority of the infants, was always negative. In 13 of the cases the mother's serum was examined for immune Rh and other irregular antibodies; and in none were such antibodies demonstrated.

The frequency of this post-mortem finding of kernicterus in premature babies led to an analysis of the clinical records of these cases, and a striking clinical similarity was found. Cases were found in all the weight ranges into which premature babies are usually classified, the smallest infant weighing 2 lb. 8 oz. Clinically, in every case the infant showed well-marked physiological jaundice; but usually they seemed to be making fair progress until 24–48 hours before death, which took place between the 5th and 9th day of life.

The most usual early signs were disinclination to feed, a tendency to vomit, and periods of cyanosis during which the respiration became shallow and irregular with apnœic periods. In many cases there was increased muscle tone with some neck and general rigidity, and occasionally twitching or actual convulsions were noted; in a few cases there was excessive flaccidity. Thermolability was greatly increased, and death was preceded by repeated cyanotic attacks and hyperpyrexia. Laryngeal swabs and post-mortem bacteriological examination confirmed the histological finding that no respiratory infection was present.

DISCUSSION

Prematurity associated with physiological jaundice and other characteristic signs, arising between the 5th and 9th day of life and resulting in death with kernicterus, seems to be a definite entity which has not been described before.

Bearing in mind the unusually great susceptibility of the tissues of the premature infant to hypoxia, the atelectasis found in some cases suggests that oxygen deficiency may be the primary factor predisposing to brain-cell damage and thus to increased permeability of certain groups of cells to bile pigment.

A further factor to be considered is the damaging influence of hypoxia on capillary permeability in the newborn (Clifford 1941); the blood-brain barrier might well be altered towards a greater concentration of bile products in the immediate vicinity of the nerve-cells in the most susceptible areas of the brain.

If, as is thought, physiological jaundice is partly due to immaturity of the liver, the premature infant is particularly liable to have a high plasma-bilirubin content. This may be an important associated factor, as Küster and Krings (1950) have suggested. These factors, which may be present in prematurity and in hæmolytic disease, suggest that in both conditions the kernicterus may have the same origin. Investigations are proceeding.

SUMMARY

In 239 consecutive post-mortem examinations following neonatal death, there were 25 cases of jaundiced premature infants in which kernicterus was found without post-mortem or serological evidence of hæmolytic disease, sepsis, or biliary obstruction.

These 25 cases seem to form a definite clinical group in which death occurred between the 5th and 9th day of life with jaundice and other characteristic physical signs.

Preliminary Communication

RHEOLOGY OF HUMAN CERVICAL SECRETIONS

EFFECTS OF MENSTRUAL CYCLE AND PREGNANCY

It has been recognised previously[1 2 3] that the physical properties of the uterine cervical mucus undergo characteristic changes throughout the sexual cycle. We have recently made further researches on the flow properties of such secretions taken from the human and bovine cervical canals with the aim of correlating these properties with the physiological states.

The instrument used is a modification of the Scott Blair[4] emptying and filling capillary-tube viscometer, which measured the varying-flow-rate as the fluid was extruded by a constant pressure. The present apparatus (originally devised for the investigation of bovine cervical secretions) makes a continuous record of the varying pressure required to extrude the material partially at a constant rate. This is a great improvement over the earlier technique in that complications due to accelerations are largely avoided. The design enables extremely small quantities to be investigated, 0 006 ml. of secretion

THE LANCET

LONDON: SATURDAY, JUNE 24, 1950

The Registrar's Plight

NOWADAYS no registrar needs telling that the road to a consultant post is hard and may prove impassable. A report from Scotland, summarised on another page, describes in arithmetical terms the poor prospect for trainee specialists in that country; and there is reason to suppose that the position in England and Wales is much the same. At the beginning of this year Scottish hospitals employed 88 junior registrars, 269 registrars, and 191 senior registrars. On the assumption that 30 vacancies for consultants will arise each year,[1] and with allowance for continuing selection, the report sets the desirable numbers in the three grades as 90, 100 (distributed over two years), and 120 (distributed over four years). Thus, even allowing for "shedding" in the middle years of training, the number of registrars and senior registrars exceeds by 169 and 71 the number appropriate if they are all to find consultant posts in Scotland.

These figures drive home a lesson that has long been known but has still to be acted on. This is simply that, with due allowance for failures for one reason or another, the number admitted to advanced training should not greatly exceed the number that can be absorbed into specialist posts in our own hospitals, in the Services, or overseas. (Openings in the Services and overseas may have been largely neglected in the last year or two, but the Scottish report argues that they do not materially alter the picture.) What the aggregate should be can only be decided nationally; and, since we now have a National Health Service, the delay in publishing the facts for England and Wales, and in forming a policy thereon, is not easily explained; for the need has been apparent for a long time.[2] Many graduates are prepared to pursue a small chance of a consultant post rather than enter general practice in its present state; and many have frankly faced the risk involved. But, in the words of the report, "it is neither fair to the individual, nor good business, to train over a period of years, and at public expense, excessive numbers of aspirants who in the event cannot find places in their chosen field." Of course, limitation of numbers need not necessarily be extended to junior registrars. Here greater latitude is reasonable; for a period in this grade enables a graduate to tell whether he likes a particular specialty (and whether it likes him), and the experience that he gains will usually be valuable in other fields, including general practice. But the position of those who have carried their specialist training further is very different. Long preoccupation with one corner of the whole field may actually make a man less competent—as well as less willing—to enter general practice than when he finished his house-appointments.

In view of these facts the Scottish report suggests first that the registrar's training should take more account of the requirements of future practitioners, and secondly that those who have been "shed" during their training should be enabled to attach themselves to hospital departments, after entering general practice. Here it touches the heart of the matter. If, as must happen, the number of registrar and senior registrar appointments is to be reduced, the loss to the hospital service will have to be made good. More consultants might be appointed; but consultant establishments have only lately been fixed, and any substantial increase at this juncture of the nation's (and the service's) affairs is likely to be resisted. At a lower level there might be an increase in the number of junior registrars, usually serving as such for only a year. (In Scotland, the number of junior registrars is actually 2 below that set as desirable.) But people of greater maturity will also be needed, and by far the most hopeful solution would be to secure part-time help from practitioners with suitable experience. To anyone considering the advantage of the service as a whole, rather than hospital work alone, it must be clear that the inconveniences of such a plan are heavily outweighed by its potential benefit to general practice. For many registrars, it seems, the road to advancement in hospital practice must shortly be closed by the termination of their present appointments; and many must be profoundly disappointed. But the tragedy lies not so much in our inability to offer them consultant appointments as in our failure, so far, to provide conditions of general practice which will enable first-rate men and women, with a high level of training, to enter it with interest and confidence. A big step towards providing such conditions would be to create or restore numerous hospital appointments to be held by general practitioners. Nothing, on the other hand, could be more disastrous to general practice than that these men and women should reluctantly take up the work of family doctors with the certainty of complete separation from the hospital work which was their first choice and for which they have laboriously trained.

Treatment of Acute Leukæmia

IN the long search for means of influencing the course of acute leukæmia, there have been many disappointments. Exsanguinotransfusion, after a brief vogue, seems to have joined the large number of treatments that have failed in the long run. The folic-acid antagonists have had a much longer trial: this is because others have confirmed the original claim of FARBER and his co-workers[1] that 4-amino-methylpteroylglutamic acid ('Aminopterin') sometimes produces temporary complete remission.

Reviews of Books

Modern Practice in Dermatology

Editor: G. MITCHELL-HEGGS, O.B.E., M.D., F.R.C.P., physician-in-charge, skin department, St. Mary's Hospital, London. London: Butterworth. 1950. Pp. 836. 63s.

HERE at last is a British work on dermatology that can compete with the large standard American textbooks. Forty-one writers have been skilfully banded together by the editor, and nothing of importance in modern dermatology has been omitted. The illustrations, nearly all black-and-white, are excellent, suggesting once more that for illustrating skin lesions colour photography cannot yet compete with really good monochromes. There is a certain amount of overlapping in the text: but with so many contributors this was almost inevitable. The book seems destined to be the standard large work of reference on dermatology in this country.

Epilepsy and Convulsive Disorders in Children

EDWARD M. BRIDGE, research professor of pediatrics, University of Buffalo. New York and London: McGraw-Hill. 1949. Pp. 670. 51s.

THE basis of this book is a clinical and statistical survey of many hundreds of epileptic children, begun by Dr. Bridge in Baltimore and completed in Buffalo. The facts resulting from this survey have been integrated and presented as a textbook. The book deals with the predisposing factors in epilepsy, the fit and its treatment, and diagnostic procedures: and an appendix gives statistical methods, forms of treatment, contents of diets, and so on. The presentation of the material is simple in the extreme, and there are many elementary charts and pictures which must be intended for interested laymen. It is indeed odd that so much valuable statistical material should be published for the first time in this setting. Most of those who work in the field of epilepsy would have welcomed a series of scientific reports dealing with the vast amount of information that Dr. Bridge has accumulated.

He is very properly concerned for the social and economic status of the epileptic, as well as with the diagnosis and scientific study and treatment of epilepsy: but the whole tenor of the book is that of the missionary and the educationist: Bridge is clearly much more interested in the epileptic than in epilepsy. It is difficult to follow the scientific theme in this setting, but there is a good index and bibliography to help the discriminating.

Conférences cliniques de rhumatologie pratique

Editor: FRANÇOIS FRANÇON. Paris: Vigot Frères. 1949. Pp. 368. Fr. 1460.

IT is three years since Dr. Françon published his first series of clinical lectures: this is its successor. The more a man knows about rheumatism, the less didactic he is, in both his writing and his teaching. Dr. Françon comes from a family with great medical traditions, and has himself had long years of clinical experience in the treatment of rheumatism. He can only offer us, he modestly says, "the keys of the kingdom": but he also allows us to open the door and get a glimpse of what is beyond. He describes the clinical picture and the treatment of conditions such as tennis-elbow (for which he advocates rest rather than movement), the different forms of osteo-arthritis of the hip, and arthritis of the thumb base, and describes in detail a picture of osteo-arthritis, new to some of us, affecting several joints in succession, a condition which he terms "la polyarthrite sèche progressive." He stresses the importance of differentiating this condition from rheumatoid arthritis manifesting itself for the first time in middle-aged and elderly people. The book contains much wise counsel about both the diagnosis of rheumatism and the management of those who suffer from it. It is simply written, and many sections are illustrated by careful case-records. An interesting final chapter notes some errors of omission and commission into which the inexperienced and the too specialised rheumatologists so often fall.

The Spiritual Physick of Rhazes

Translated from the Arabic by Prof. A. J. ARBERRY, LITT.D. London: John Murray. 1950. Pp. 110. 4s.

The Spiritual Physic of Rhazes, the greatest medical genius of his age—he died just over a thousand years ago—is here translated from the original Arabic for the first time. A physician in charge of a great hospital in Bagdad, and a voluminous writer upon what he calls "the Bodily Physick," Rhazes feels the need to address himself also particularly to "the Spiritual Physick." These early efforts of a cultured Persian physician of great experience towards the study of psychotherapeutics, translated into graceful and flowing English, can hardly fail to be of interest, for the book contains both a searching analysis of human character and a series of wise prescriptions for moral improvement and reform.

Current Therapy 1950

Editor in Chief: HOWARD F. CONN, M.D. Philadelphia and London: W. B. Saunders. 1950. Pp. 736. 5s.

THE rapid progress in therapeutics makes it difficult for the general practitioner to keep up to date. The ambitious aim of this volume, the successor to *Current Therapy 1949*—and the precursor, we hope, of further annual volumes—is to bring to the practising physician authoritative information on the latest accepted methods of treatment. The routine used in various American hospitals in all the common medical, and in many surgical conditions is fully described by those who actually control the treatment. The monographs are concise and clear, and cover specific, general, and dietetic therapy. Where no one technique has been universally adopted, two or more methods, from various hospitals, are described. The result is a valuable book of reference.

Troubles fonctionnels de l'appareil génital de la femme (3rd ed. Paris: Masson. 1949. Pp. 1050. Fr. 3700).—This readable book by Prof. Gaston Cotte, of Lyons, covers very thoroughly the physiology and pathology of menstruation. A large section of it deals with sterility, and, as would be expected, he devotes a long chapter to the nervous disorders of the uterus and appendages, a subject which he has explored more thoroughly than any living authority. The book is really a volume of medical gynæcology with special reference to endocrinology, as the title suggests: operative procedures in general receive small attention. Physiotherapy and hydrotherapy are given a more important place in the treatment than is customary here; and British gynæcologists may find the chapter on disorders of the circulation of the genital tract somewhat hypothetical. The general standard is good, but the work will be of value only to the advanced student or the established consultant.

Unipolar Lead Electrocardiography (2nd ed. London: Henry Kimpton. 1949. Pp. 392. 52s. 6d.).—The second edition of Dr. E. Goldberger's book is twice the size of the first, but there is no fundamental change or addition. It contains more diagrams and a new section on the arrhythmias, to which, however, unipolar leads contribute little. Theoretically, unipolar leads should be superior to bipolar leads, but in practice the difference does not seem to be great. However, unipolar precordial leads are now used fairly generally, and, as they may be taken quite as conveniently as the precordial lead paired with a limb, there is little to be said for retaining the latter method. On the other hand, the interpretation of the unipolar limb leads is still in a hypothetical stage and the case for their routine use in place of, or in addition to, the standard limb leads is not yet established. Occasionally Dr. Goldberger is unfair in giving credit to a unipolar lead for allowing a diagnosis which is quite plainly given by the standard leads, and it is hard to find an example in this book where unipolar limb leads give important information not obtainable by other methods. Indeed the unipolar cardiogram is sometimes interpreted only by information obtained by clinical examination or postmortem findings. Sometimes his illustrations show that almost identical patterns are obtained from dissimilar cardiac conditions, and the theoretical reasoning used for their interpretation is less convincing than the evidence from physical examination. But though unipolar limb cardiography has a long way to go, it is a developing method, and this book is an important exposition of the subject.

THE LANCET

LONDON: SATURDAY, JUNE 24, 1950

The Registrar's Plight

NOWADAYS no registrar needs telling that the road to a consultant post is hard and may prove impassable. A report from Scotland, summarised on another page, describes in arithmetical terms the poor prospect for trainee specialists in that country; and there is reason to suppose that the position in England and Wales is much the same. At the beginning of this year Scottish hospitals employed 88 junior registrars, 269 registrars, and 191 senior registrars. On the assumption that 30 vacancies for consultants will arise each year,[1] and with allowance for continuing selection, the report sets the desirable numbers in the three grades as 90, 100 (distributed over two years), and 120 (distributed over four years). Thus, even allowing for "shedding" in the middle years of training, the number of registrars and senior registrars exceeds by 169 and 71 the number appropriate if they are all to find consultant posts in Scotland.

These figures drive home a lesson that has long been known but has still to be acted on. This is simply that, with due allowance for failures for one reason or another, the number admitted to advanced training should not greatly exceed the number that can be absorbed into specialist posts in our own hospitals, in the Services, or overseas. (Openings in the Services and overseas may have been largely neglected in the last year or two, but the Scottish report argues that they do not materially alter the picture.) What the aggregate should be can only be decided nationally; and, since we now have a National Health Service, the delay in publishing the facts for England and Wales, and in forming a policy thereon, is not easily explained; for the need has been apparent for a long time.[2] Many graduates are prepared to pursue a small chance of a consultant post rather than enter general practice in its present state; and many have frankly faced the risk involved. But, in the words of the report, "it is neither fair to the individual, nor good business, to train over a period of years, and at public expense, excessive numbers of aspirants who in the event cannot find places in their chosen field." Of course, limitation of numbers need not necessarily be extended to junior registrars. Here greater latitude is reasonable; for a period in this grade enables a graduate to tell whether he likes a particular specialty (and whether it likes him), and the experience that he gains will usually be valuable in other fields, including general practice. But the position of those who have carried their specialist training further is very different. Long preoccupation with one corner of the whole field may actually make a man less competent—as well as less willing—to enter general practice than when he finished his house-appointments.

In view of these facts the Scottish report suggests first that the registrar's training should take more account of the requirements of future practitioners, and secondly that those who have been "shed" during their training should be enabled to attach themselves to hospital departments, after entering general practice. Here it touches the heart of the matter. If, as must happen, the number of registrar and senior registrar appointments is to be reduced, the loss to the hospital service will have to be made good. He stresses the importance of differentiating this condition from rheumatoid arthritis manifesting itself for the first time in middle-aged and elderly people. The book contains much wise counsel, about both the diagnosis of rheumatism and the management of those who suffer from it. It is simply written, and many sections are illustrated by careful case-records. An interesting final chapter notes some errors of omission and commission into which the inexperienced and the too specialised rheumatologists so often fall.

The Spiritual Physick of Rhazes

Translated from the Arabic by Prof. A. J. ARBERRY, LITT.D. London: John Murray. 1950. Pp. 110. 4*s.*

The Spiritual Physic of Rhazes, the greatest medical genius of his age—he died just over a thousand years ago—is here translated from the original Arabic for the first time. A physician in charge of a great hospital in Bagdad, and a voluminous writer upon what he calls "the Bodily Physick," Rhazes feels the need to address himself also particularly to "the Spiritual Physick." These early efforts of a cultured Persian physician of great experience towards the study of psychotherapeutics, translated into graceful and flowing English, can hardly fail to be of interest, for the book contains both a searching analysis of human character and a series of wise prescriptions for moral improvement and reform.

Current Therapy 1950

Editor in Chief: HOWARD F. CONN, M.D. Philadelphia and London: W. B. Saunders. 1950. Pp. 736. 50*s.*

THE rapid progress in therapeutics makes it difficult for the general practitioner to keep up to date. The ambitious aim of this volume, the successor to *Current Therapy 1949*—and the precursor, we hope, of further annual volumes—is to bring to the practising physician authoritative information on the latest accepted methods of treatment. The routine used in various American hospitals in all the common medical, and in many surgical, conditions is fully described by those who actually control the treatment. The monographs are concise and clear, and cover specific, general, and dietetic therapy. Where no one technique has been universally adopted, two or more methods, from various hospitals, are described. The result is a valuable book of reference.

Troubles fonctionnels de l'appareil génital de la femme (3rd ed. Paris: Masson. *1949.* Pp. 1050. Fr. 3000.). This readable book by Prof. Gaston Cotte, of Lyons, covers very thoroughly the physiology and pathology of menstruation. A large section of it deals with sterility, and, as would be expected, he devotes a long chapter to the nervous disorders of the uterus and appendages, a subject which he has explored more thoroughly than any living authority. The book is really a volume of medical gynæcology with special reference to endocrinology, as the title suggests; operative procedures in general receive small attention. Physiotherapy and hydrotherapy are given a more important place in the treatment than is customary here; and British gynæcologists may find the chapter on disorders of the circulation of the genital tract somewhat hypothetical. The general standard is good, but the work will be of value only to the advanced student or the established consultant.

Unipolar Lead Electrocardiography (2nd ed. London: Henry Kimpton. 1949. Pp. 392. *52s. 6d.*).—The second edition of Dr. E. Goldberger's book is twice the size of the first, but there is no fundamental change or addition. It contains more diagrams and a new section on the arrhythmias, to which, however, unipolar leads contribute little. Theoretically, unipolar leads should be superior to bipolar leads, but in practice the difference does not seem to be great. However, unipolar precordial leads are now used fairly generally, and, as they may be taken quite as conveniently as the precordial lead paired with a limb, there is little to be said for retaining the latter method. On the other hand, the interpretation of the unipolar limb leads is still in a hypothetical stage and the case for their routine use in place of, or in addition to, the standard limb leads is not yet established. Occasionally Dr. Goldberger is unfair in giving credit to a unipolar lead for allowing a diagnosis which is quite plainly given by the standard leads, and it is hard to find an example in this book where unipolar limb leads give important information not obtainable by other methods. Indeed the unipolar cardiogram is sometimes interpreted only by information obtained by clinical examination or postmortem findings. Sometimes his illustrations show that almost identical patterns are obtained from dissimilar cardiac conditions, and the theoretical reasoning used for their interpretation is less convincing than the evidence from physical examination. But though unipolar limb cardiography has a long way to go, it is a developing method, and this book is an important exposition of the subject.

Salicylate in Rheumatic Fever

In the seventy-five years since Buss[1] and Maclagan[2] introduced salicylate it has been established beyond question that the drug dramatically reduces the pain and pyrexia of acute rheumatic fever. But there is still no agreement on the far more important question: Does salicylate in any way protect the patient against the crippling valve lesions that follow rheumatic carditis? Coburn,[3] who gave massive, almost toxic, doses and relied largely on the erythrocyte-sedimentation rate (E.S.R.) as a test of cure, concluded that if salicylate is given early enough, long enough, and in large enough amounts it can cure carditis. He has received some support from Reid,[4] but other observers[5, 6] have been unable to confirm his findings. In this respect there is as yet no published evidence that 'Cortisone' is any more effective than aspirin. The several clinical reports[7] that have appeared are all careful not to claim that cortisone or adrenocorticotropic hormone has a greater effect on rheumatic carditis than can be explained as a result of the reduced load on the heart with the decrease in fever. Nevertheless, by deduction from the known non-specific action of cortisone in suppressing the formation and maturation of all forms of granulation tissue, there is good reason to hope that the pathological changes of rheumatic carditis can be aborted by the early administration of this drug. But both cortisone and salicylate await a statistical study with long-term evaluation, comparing the course of the treated with the untreated disease. This would be difficult to arrange, since it would mean depriving some patients with pain and fever of the undoubted immediate benefits of salicylate. Yet there is no other way of obtaining a satisfactory answer to our question; for the natural history of rheumatic fever is so variable that any apparent cure may be but a natural remission, whereas a real cure might be masked by exposure to a fresh group-A streptococcal infection with subsequent recurrence of the disease.

As Buss noted, the effect of salicylate on pain and fever is manifest in diseases other than rheumatic fever; but it is so striking in this disease that it has long been suspected that the drug has a specific effect on the rheumatic process as well. In addition, salicylate in high dosage depresses the E.S.R. in rheumatic fever,[3, 4, 8] though again a similar but slighter effect has been demonstrated in other diseases.[5, 9] In their recent study of the distribution of the body-fluids in rheumatic fever, Reid and his colleagues[10] claim that salicylate induces a pronounced shift in body-fluids, so that with the relief of pain and swelling of the affected tissues there is a reduction in intracellular fluid and an increase in plasma volume. This effect may be so great that in moderate salicylate intoxication signs of tissue dehydration may develop at a time when the plasma volume is raised to 150% of the figures found on recovery. Indeed this increase in plasma volume may itself be so heavy a load on an already damaged heart that pulmonary œdema supervenes.

Some light is thrown on the mechanism of this fluid shift by the work of Swyer,[11] who showed that salicylate seems to reduce the permeability of damaged capillaries and therefore decrease the loss of fluid from them. Smith and Humphrey[12] suggest that this action in reducing capillary permeability may explain their findings that salicylate protects experimental animals against the tissue necrosis that follows the reversed Arthus and Schwartzman reactions. These reactions depend on the hypersensitivity of connective tissue to which an antigen has been affixed by local injection. Again, some observers[13] contend that salicylate protects against the arterial and myocardial lesions that occur in serum myocarditis, though this opinion is not unanimous.[14] It is not certain that there is a hypersensitivity of the connective tissue in rheumatic fever, but many think it highly probable. If these views are correct, salicylate seems to act on that final common pathway of these connective-tissue reactions which involves increased capillary permeability. It may be because of the same effect on capillary permeability that salicylate inhibits the increase in the spreading action of hyaluronidase which occurs in rheumatic fever; for the increase may merely depend on a greater flow of tissue fluids as a result of increased capillary permeability.

Thus evidence is accumulating to show that the action of salicylate in rheumatic fever depends on local tissue reactions, and it is highly important that such effects should be investigated in other disease processes in man as well as experimentally in animals.

Hospital Life

No-one can live and work for long in a large hospital without becoming aware that he is in the midst of various hierarchies, held together by a common purpose, yet divided by the exclusive lore of each. A report[15] on employment relations in a group of hospitals in Lancashire brings out some of the tensions engendered by the system. It is noteworthy that, according to this study, the smaller the hospital the higher the morale; for in the smaller units life is likely to be less highly formalised. The report draws attention to much else that we should bear in mind: the demand for joint consultation (now, happily, to be satisfied[16]); the need for a clear and encouraging policy governing promotion, and for better catering and a more satisfying social life; and the wish of nurses that shift work shall be substituted for the broken periods of duty which now bar them from true leisure. That 50% of student nurses were found to leave in their first year, suggests that selection is less rigorous than it might be.

Unfortunately, these reports have often covered only short periods of observation; and opinions have differed on what constitutes a remission. Nevertheless, the reports give the impression that clinical and hæmatological remissions—admittedly temporary—were too common to be purely spontaneous.

In order to gain a more balanced view, SACKS and his associates [2] carefully observed 14 patients with acute leukæmia over a period of twelve months. The diagnosis was based on examination of the peripheral blood *and* the bone-marrow. Complete temporary remission was recorded only if both blood and bone-marrow returned to normal; at the same time there would be remission of any anæmia, a return of the platelet-count to normal, decrease in the size of enlarged spleen or lymph-glands, and cessation of hæmorrhages. With only some of these improvements, and particularly when the peripheral blood appeared normal but abnormal cells were still numerous in the bone-marrow, "partial temporary remission" was recorded. "Clinical remission," in which the patient felt better but neither blood nor bone-marrow returned to normal, was rightly disregarded. Of their 14 patients, 6 were children up to 8 years of age, 2 were adolescents, and 6 were adults between 26 and 63 years of age. Of the whole group, 7 were diagnosed as having lymphatic leukæmia, while the myeloid form was found in 4 and the monocytic in 3. The patients were treated with aminopterin intramuscularly, 0·5–2 mg. daily; and instead, some received a few doses of 'Amethopterin' for a short time, but this antagonist did not seem to have any advantages. Of the 14 patients, only 2 had complete temporary remissions; partial remissions took place in 3, who all died later; and in 9 there was no response. The 2 cases which remitted were in an adult, aged 39, and a child, aged 14 months; in each case the remission lasted about 3 months, after which the patients relapsed and died, further aminopterin having no effect. Another, and larger, group has been studied by STICKNEY and his colleagues,[3] who treated 21 children and 33 adults with aminopterin; some amethopterin was used, but this was soon given up because it seemed less active and more toxic than aminopterin. They gave 1 mg. of aminopterin, orally or intramuscularly, each day until toxic effects appeared or remission was induced. By SACKS's criteria, among the 21 children, there were 5 complete temporary remissions, lasting 1–3 months; and among the 37 adults, 3, lasting 3–4 months. With 1 exception, all these cases relapsed and would not respond to further treatment; the single exception was a 5-year-old child who had 3 remissions and relapses and was still alive 14 months after the initial treatment. The report notes that, though abnormal cells in the bone-marrow were greatly reduced, they were never completely absent; and the effectiveness of the folic-acid antagonist is shown by the appearance of typical megaloblasts in some cases.

The results obtained by these two groups of workers are typical, and discouraging. It is clear from the case-records that to obtain a remission with aminopterin the drug was pushed up to and beyond the limit of tolerance. Toxic effects, such as ulcerative stomatitis, diarrhœa, alopecia, and an exaggerated hæmorrhagic diathesis, were quite frequent. All the patients had to be given supporting blood-transfusions and antibiotics to prevent or treat secondary infections. The margin between the dose that may induce a remission and the dose that will cause marrow aplasia is very narrow. No criterion for predicting which cases are likely to remit has emerged, though lymphoid types seem to be most responsive, and monocytic types least. Another serious disadvantage is that few cases will respond to even a second course of aminopterin. (Cells of transmitted mouse leukæmia that were initially sensitive to amethopterin became resistant quite quickly.[4]) There are many possible folic-acid antagonists besides aminopterin and amethopterin; the difficulty is to select those that combine minimum toxicity with maximum efficacy. Unfortunately, "screening" by testing on experimental mouse leukæmia has not proved satisfactory, because of the species difference—in mice amethopterin was found to be the best antagonist for this purpose.

Despite all these difficulties, work with folic-acid antagonists is likely to continue; and further studies may tell us how the remissions are produced. Much credit must go to those manufacturers who have used their resources for this relatively unrewarding field. Meanwhile, it is not surprising to learn that adrenocorticotropic hormone (A.C.T.H.), which is known to cause a reduction in lymphoid tissue, has been tried in acute leukæmia. A preliminary report by DAMESHEK and others [5] deals with 8 patients, 2 with subacute myeloid, and 6 with acute or subacute lymphoid, leukæmia. The myeloid cases were unaffected. The 1 case of lymphatic leukæmia in an adult was probably too far advanced to respond; but the 5 children had remissions, and in 4 of them the bone-marrow became normal or almost normal; the remissions were accompanied by a rise in reticulocytes and platelets, suggesting that the A.C.T.H. actually stimulated the remaining normal marrow. Experience with this substance in other conditions suggested that if treatment with it were stopped a relapse would follow; in 1 patient treatment was stopped and a relapse did in fact ensue. It must be noted that all of DAMESHEK's cases which remitted were of the "leucopenic" type, and it is not clear whether the same results will be seen in the classical types. DONOHUE and others [6] have reported the case of a boy, aged 7, who had an eosinophilic type of myeloid leukæmia with many myeloblasts in the bone-marrow. The response to A.C.T.H. was good, as judged by the disappearance of eosinophils from the blood and reduction of myeloblasts in the bone-marrow from 88 to 8·5%. Side-effects appeared early, however, and were troublesome so treatment was discontinued after a month. During the next 13 weeks the blood condition slowly relapsed, and it was reported to be responding less well to a second course.

At present, then, two lines of research are being explored. These offer at least some dim hope that acute leukæmia may eventually be controlled.

secretary, an animal secretary, and a treasurer of doubtful status—a pleasantry which was accepted without rancour by Dr. G. I. M. Swyer, Mr. Arthur Walton, PH.D., and Dr. W. J. Tindall, the officers in question.

The conference presented the usual record of careful work. Dr. R. G. Harrison and Dr. A. G. Oettlé, in studying pathological changes in the rat testis following ischæmia, have found that temporary ischæmia, induced by clipping the vas and its attendant vessels, is followed by temporary sterility. Dr. Parkes discussed the storage of mammalian spermatozoa at low temperatures, the essential process for success being immediate and complete freezing to a temperature of −79°C. Dr. Margaret Hadley Jackson asked the significance of clusters of round cells which she had found in the endometrium of a few "stubbornly infertile women." This patchy infiltration is found at almost any level in the endometrium and is not confined to any particular phase in the menstrual cycle. She distinguished it from the dense infiltration found before and after menstruation starts, from postabortal, postpartum, or gonococcal endometritis, and from the infiltration seen with carcinoma and in senile endometritis, and also—though less certainly—from tuberculosis of the endometrium. Mr. L. M. Snaith, F.R.C.O.G., had found that this appearance was often associated with pelvic inflammation—sometimes an old healed lesion—elsewhere than in the uterus. Miss Josephine Barnes, F.R.C.S., recalled that pathologists are apt to vary in the proportion of cases of tuberculous endometritis which they report. In regular menstruators the endometrium is shed monthly. One month a biopsy may be positive for tuberculosis, and the next it may be negative, in spite of the presence of active disease.

Dr. Claude Béclère, who showed a film illustrating the use of hysterosalpingography in the diagnosis and treatment of sterility, believes it is important to limit the amount of radiopaque material injected, to control the procedure by screening during the injection, and to distinguish between the spilling from a patent tube and the slow filling of a hydrosalpinx. Patency of tubes can be confirmed for certain by taking a control film one or two days after the injection, but Dr. Bernard Sandler attempts to complete the investigation at one session by introducing into the rectum a plastic instrument roughly 8 in. long and $^1/_2$ in. in diameter, with a radiopaque marker in the tip; the fallopian tube can be massaged against this firm object (the position of which can be checked by looking at the marker), and a patent tube will then spill its contents. Dr. Béclère expressed his interest in this method, but again stressed the importance of excluding hydrosalpinx.

EMIGRATION OF BACTERIA FROM THE GUT

PERITONEAL irrigation with slightly hypertonic fluid is often used for patients with acute renal failure or uræmia, but the treatment has its dangers.[1] Despite the most careful technique a *Bact. coli* peritonitis may supervene, and we need to know why. It has been shown that if sterile but irritant fluids, such as a solution of gum tragacanth or 5% monoethanolamine oleate, are injected intraperitoneally in dogs, coliform organisms can eventually be recovered from the peritoneal cavity. In uræmic dogs long-continued dialysation of the peritoneum leads to peritonitis caused by coliform organisms or other intestinal bacteria, and yet blood-cultures taken from these dogs are sterile; so it seems probable that bacteria have migrated through the wall of the gut into the peritoneal cavity.

The hypothesis of transmural migration, which has an obvious clinical bearing, has now been tested by Schweinburg and his colleagues[2] in dogs by introducing bacteria tagged with radioactive iodine into the gastro-intestinal tract after treating the peritoneum with a chemical irritant. The iodination of washed bacteria with I^{131} apparently did not affect their viability, but it is not known whether the reaction occurs on the surface or in the interior of the bacterial cell. The breaking down of tagged organisms will produce soluble radioactive protein, but if the organisms themselves remain in the gut little radioactive material should reach the peritoneal exudate. In a control group of dogs Schweinburg and his co-workers first gave radioactive iodine by stomach-tube and found that very little of this reached the peritoneal cavity, whereas when labelled coliforms were injected intravenously ten times as much radioactive material appeared there. The difference reflects the rapid elimination of ionic iodine in the urine and the slow disintegration and elimination of bacterial substances. In another group of dogs to which tagged bacteria were given by stomach-tube before the peritoneal fluid became contaminated the amount of radioactivity subsequently found in the exudate was small; but if coliforms were already present in the exudate when the labelled organisms were given, whether these were dead or alive, something like 1000 times as much radioactive material appeared in the exudate, the amount that could be recovered from the peritoneal fluid being 0·5–4% of the total radioactive bacterial substance introduced.

These findings support the contention that coliforms migrate into the peritoneal cavity when the intestinal coat is irritated by chemical substances. Since dead as well as living bacteria make the journey, their migration must be a passive transfer in the flow of fluid across the serosa. In patients with uræmia treated by dialysis it seems likely that the same mechanism is responsible for the occurrence of peritonitis; if so it should be possible to prevent this complication by giving streptomycin by mouth or one of the other drugs which "sterilise" the intestinal contents.

DANISH TREATMENT OF PSYCHOPATHS

THOSE who have not had the chance of visiting Denmark's psychopathic prison had the prison brought to them on June 6 when Dr. Georg Stürup showed his documentary film at the Institut Français. The showing was sponsored by the Institute for the Scientific Treatment of Delinquency and the Howard League for Penal Reform, the chair being taken by Lord Justice Denning, deputising for the Attorney-General. The film is a product of the Government Film Committee, the Danish equivalent of our C.O.I. Films Division; it is beautifully photographed by Annelise Reenberg; and largely written and acted by the psychopathic detainees themselves. The hero is the psychopathic criminal Jensen, who finally leaves the old court-house of Denmark a wiser, a better, and a free man. Happily he is not a sexual offender, so there is no call for him to submit to castration, though the method which is employed in the Herstedvester Institution is graphically illustrated. By some strange psychopathological trick, the recovering castrati are shown tending a button-mushroom farm—the button-mushrooms being almost identical with the glass pseudo-testicles so recently inserted, and photographically painfully reminiscent of the real thing so recently departed.

These psychopaths are fascinating folk. Their characteristics emerge admirably in the film—the over-determined gait, the over-manly chewing of the pipe and furrowing of the forehead, the egocentricity, the petty lies and silly sulks, the lack of facial mobility. The film shows dramatically the contrast between the pleasant environment of Herstedvester (recalling a modern English borstal), and the slow realisation by the detainee that he is in for good, unless he can come to terms with society. Dr. Stürup emphasises that the

BREAST-MILK

DURING the late war a very large number of analyses of breast-milk were made at the National Institute for Research in Dairying, for the purpose mainly of assessing the nutritional state of the mothers. Kon and Mawson, and their many collaborators in this study, first sought a means of telling how far the constituents of the milk were a measure of the mother's nutrition. They investigated the normal range of variation and the effect of supplements and deprivations: and they charted the variations in the course of lactation. The results, which have now been published,[1] indicate where our national feeding habits may lead a mother into taking less of a vitamin than she is giving to her baby.

The analyses were mostly of vitamins. Vitamin D is present in breast-milk only in almost undetectable quantities, even where the mother's intake is ample; and breast-fed as well as bottle-fed babies should receive supplements. Vitamin C, as was known, is present in higher concentration in milk than in plasma. A detailed study of food intake and milk secretion of one mother showed that the milk vitamin-C content responds only slowly to increased intake of this vitamin, and similarly the milk content is only slowly depressed by deprivation. For five weeks during which the mother took only 10 mg. daily, the amount in the milk fell continuously, but in these weeks she secreted about 0·5 g. more of the vitamin than she received. (Incidentally, the point where a consignment of oranges arrived in this country shows clearly in the survey.) The B vitamins differ from each other in their behaviour. Supplements of riboflavine have a quick and brief effect on the concentration in the milk, which may be altered by each meal. The thiamine concentration, on the other hand, varies very little with food supplements and remains fairly constant throughout lactation and when the mother ate more thiamine the effect was more evident in the concentration of the free than of the combined form. The strange thing about this vitamin is that the concentration of it is lower in the milk of young and of old mothers; and it is also low where the mother has little milk—a feature which recalls the suggestion by Knott et al.[2] that nervous factors may influence the concentration.

The fat content of milk varies with the technique of taking the sample; and so Kon and Mawson have related the concentration of vitamin A to the fat content, and not to the volume, of milk. Definite trends emerge: there is a continuous fall in concentration during the first twenty weeks of lactation and a consistent increase with increasing maternal age, independent of parity—a phenomenon which remains unexplained. The taking of one large dose of the vitamin is reflected in the concentration in the milk for a day or more. The carotenoids—the substances responsible for the yellow colour of colostrum and milk—apparently dwell in the capsule of the fat globules. Unlike vitamin A, their concentration in the milk remains unaltered throughout lactation, though varying from day to day. β-carotene is present in such small quantities that its contribution to the baby's vitamin-A supply is negligible.

The practical implications are that a mother should take her vitamin-A tablets during lactation, that with the B vitamins her needs are well met by the national loaf and by the extra rations she gets, and that she should certainly eat fresh fruit and not despise green vegetables.

TOTAL SYMPATHECTOMY

THE original purpose of operations for hypertension was to reduce the blood-pressure to normal, and since the fall of blood-pressure is more or less proportional to the extent of the sympathectomy the operations became more and more extensive. In 1941 Grimson[1] reported 3 cases in which he had performed "total" bilateral sympathectomy, removing the sympathetic chains from the stellate ganglion to L3 on both sides. But after studying 30 cases Ray and Console[2] conclude that, except in exceptional circumstances, the greater lowering of blood-pressure attained does not offset the higher morbidity-rates and mortality-rates which accompany the total when compared with the standard thoracolumbar sympathectomies. Smithwick[3] supports this view, and records that 4 out of 16 of his patients were quite unable to stand after total sympathectomy. It is becoming clear, in Britain at least, as recent letters in these columns have emphasised, that the primary aim of treatment in *advanced* cases of hypertension is to relieve symptoms, especially headache, and that reduction of blood-pressure is a secondary consideration. For this purpose quite limited sympathectomies are effective. In early cases it is arguable that adequate denervation of the kidneys is all that is required, and this can be achieved by thoracolumbar sympathectomy.

Is there then any place for "total" sympathectomy? Ray and Console believe that the indications are: (1) hypertension associated with angina of effort; (2) postural hypotension with severe tachycardia after less extensive operations; and (3) severe vasospastic conditions in the hands, accompanying hypertension or appearing after a thoracolumbar sympathectomy. In the first group the prognosis is poor, and many would hold that no operation is justified. Lowering of the blood-pressure may itself precipitate or aggravate angina pectoris. Before deciding on total bilateral sympathectomy, removal of the stellate and upper four thoracic ganglia on the left side alone should be considered. This operation, by dividing the afferent pain fibres from the heart, may give satisfactory relief of symptoms. As regards the second group of cases, the effects of postural hypotension usually pass with time and can largely be controlled with a corset and elastic stockings. If troublesome tachycardia on standing persists, the same limited high thoracic sympathectomy on the left may be done with the object of dividing the cardiac motor nerves. Lastly, Raynaud's phenomenon in the hands after thoracolumbar sympathectomy is rarely severe enough to call for further surgery—Shucksmith[4] makes the interesting observation that if the third thoracic ganglia are removed (presumably in a supradiaphragmatic operation) it does not occur. If the vascular spasm was present *before* thoracolumbar sympathectomy it may become very severe afterwards and demand more extensive procedures. But even then total sympathectomy seems rather drastic.

A NEW SOCIETY

BIOLOGISTS, veterinarians, physiologists, and doctors have all contributed to the study of fertility; and for some years now representatives of these disciplines have held an annual conference to exchange views and lighten each other's way. The seventh of these conferences was held on June 16 and 17 in the Zoological Society's house in London, and the mating of so many fertile minds was then blessed with the birth of a new scientific body—the Society for the Study of Fertility. Mr. A. S. Parkes, D.SC., F.R.S., the first president, remarked, at the annual dinner, that the society had provided itself with a human

THE ROYAL COLLEGE OF SURGEONS THROUGH 150 YEARS

NEXT week the Royal College of Surgeons of England is celebrating the 150th anniversary of the charter which constituted it a Royal College.

A Guild of Barbers is mentioned in the records of the City of London in 1308 and a Fellowship of Surgeons in 1369. In 1493 the latter entered into an alliance or "composition" with the Barbers Company, the two being formally united by Act of Parliament in 1540. The partnership was dissolved by an Act of Parliament in 1745, which constituted the "Master, Governors and Commonalty of the Art and Science of Surgeons of London."

The present unanimity of applause for the celebration of the 1800 charter is in marked contrast to its birth-throes and early infancy. The Surgeons obtained the charter of 1800 because they had failed to secure a private Bill in Parliament. Certain technical irregularities about the acquisition of premises in Lincoln's Inn Fields and the sale of the dilapidated Surgeons' Hall near the Old Bailey had led to a Bill being presented in 1797 to convert the company into a Royal College. But when the Bill came up for its third reading in the House of Lords, it was rejected after a violent speech by Lord Thurlow, who may have been influenced by the fact that he had a house near the new hall. The inhabitants of Lincoln's Inn Fields did not like the idea of dissections being carried on in what was a residential neighbourhood. Thurlow has been described as not only vulgar, arrogant, and profane, but also immoral. Perhaps, however, he had some justification for his fears about the presence of the college in Lincoln's Inn Fields, for in 1803 his old house was acquired to accommodate the Hunterian Museum.

Eventually it was decided not to proceed with a private Bill but to obtain a Royal Charter. The petition for this was presented in March, 1798, and the charter passed the Great Seal on March 22, 1800.[1] This constituted the Royal College of Surgeons of London. A further charter in 1822 changed the titles of master and governor to president and vice-president, and converted the court of assistants into a council.

But more controversy was to come, and its spokesman was Thomas Wakley.[2] THE LANCET, under his editorship, attacked the regulation of the council regarding medical students, which, Wakley said, created a monopoly to the benefit of council members. It also attacked the undemocratic nature of the self-electing council. Twelve hundred persons attended a protest meeting organised by Wakley at the Freemasons' Tavern in February, 1826. Strong language was used and on one occasion Wakley was thrown out of the college in a free fight. Eventually, however, Wakley and the general pressure of public opinion secured a further charter in 1843, which set up a new class of membership—the Fellows—from and by whom the council was to be elected, and broadened the court of examiners. It also changed the name to the Royal College of Surgeons of England. Even in 1889, however, there was a test case about the right of members to hold meetings at the college.

During the 19th century distinguished leaders of the profession served as presidents of the college, which increased in stature and influence. In 1886 the practice of electing a different president each year was discontinued. Sir William Scovell Savory, elected in 1885, was re-elected each year until he retired in 1888. At the turn of the century Sir William MacCormac filled the office from 1896 until the end of the centenary year, 1900. Lord Moynihan, who was first elected president in 1925, breathed new life into the college, restarting the research work: he was president for six years. His term of office was exceeded by that of Lord Webb-Johnson (1941-48), who, entering office in the war years, saw the post-war controversy on the health service, in which the presidents of the Royal Colleges played an important part at a critical stage. He was responsible for the great development of the college's postgraduate work during his term. Sir Cecil Wakeley, elected president last year, presides over a college comprised of some 3300 fellows and 25,000 members in all parts of the world.

THE COLLEGE AND EDUCATION

The Royal College of Surgeons has always been concerned with education. In the last century its attention was devoted to undergraduate medical schools, but with the growth of the medical faculties of universities and the establishment of the General Medical Council, the emphasis, as with other medical corporations, has shifted to the postgraduate student. The increasing popularity of the higher examinations is shown by the fact that the numbers in 1938–39 taking primary fellowship were 439 and the final examination 469; in 1949, 814 sat the examination for the former and 790 for the latter. The number of passes in 1938-39 was

secret of his success-rate—nearly 50% in his first 300 cases—is above all the indeterminate sentence. Without this fierce stimulus, the psychopath will make no effort to grow up and face the world as it is.

The details of the work and the theoretical basis of treatment at Herstedvester have been described in our columns by Taylor.[1] Dr. Stürup had some additional information to add. The cost of Herstedvester is about £1 per day per detainee—a high figure, but not the highest among world criminal institutions (the average for the ordinary Danish prisons is 10s. a day). Sterilisation is occasionally performed in Herstedvester in non-sexual psychopaths, usually because they have requested it to relieve the anxiety that they may have children like themselves. It is never done without full discussion first with the detainee's wife. For sexual offenders, castration is usual. A number of the castrati have subsequently married, and some are able still to perform the sexual act on occasion. The wives are often divorced women who have had, in Dr. Stürup's words, "more than enough of sex with their previous husbands." Such marriages are remarkably successful.

The lesson of Herstedvester is not that we should follow the Danish example with the sexual offender. It is rather that the psychopathic criminal is the toughest nut in both the penal and psychiatric calendars. The only hope lies in a combination of rigorous occupation, psychiatric understanding, and absolute toughness. For these people, prisons without bars are useless. Unless the detainee can be brought to see that his only hope of release is that he shall change himself, nothing can be done. It was good to see a number of the senior officials of our Prison Commission in Dr. Stürup's audience.

INFERTILITY IN CATTLE

THE fertility of our dairy herds is said to be decreasing. Reliable statistics are difficult to obtain, but the falling off seems to be particularly severe among pedigree cattle—the very ones in which a rapid increase in number is most desirable. Various explanations—genetic, endocrine, nutritional, and so on—have been suggested, but none is likely to be convincing until carefully planned experiments have been made. One suggestion is a dietary deficiency. The necessity for generous feeding of breeding stock is part of the stock-breeder's traditional knowledge, and it would be absurd to suggest that our pedigree cattle are underfed. Over a long period, however, it seems probable that a specific dietary deficiency might cause a deterioration in their fertility without other symptoms.

In the past, the difficulty encountered in getting cows into calf during the winter months used to cease with the advent of spring grass. But on the modern farm spring grass is not the old grass mixture of the fields and water-meadows but a ley growing on land that is mostly fertilised from sacks instead of the dung-cart. Through the work of Stapledon the food value of modern grass crops has undoubtedly been much improved, but there is no denying that the best dairy herds, whose reproductive-rate is apparently falling most sharply, are those that are increasingly fed by the new methods. May the crops so produced be lacking in some reproductive factor?

The disastrous experience of sheep-farmers in Western Australia, and the finely coordinated investigations that it inspired, revealed another and perhaps more likely mechanism by which infertility might result from modern methods of pasture improvement. It will be recalled[2] that the fertility of the flocks in that part of Australia declined so severely that many owners gave up sheep-farming. In spite of repeated mating with rams of proved fertility a large proportion of the ewes remained sterile. Where conception did occur, the fœtus sometimes died in utero. The infertile ewes were found to have a cystic hyperplasia of the endometrium, and uterine prolapse was common in non-breeding ewes. The most informative finding was that some virgin females and castrated males had well-developed teats and udders, such as can be produced by treatment with œstrogens. The sheep were clearly ingesting some œstrogenic substance from the pastures, and this was finally traced to the subterranean clover which had been introduced a few years previously to improve the pastures and had flourished exceedingly. Workers at the Courtauld Institute of Biochemistry and the National Institute for Research in Dairying have established that some English herbage also contains potent œstrogens. Is it possible that these are affecting the fertility of our pedigree cattle?

ENTERTAINMENT UNDER LOCAL ANÆSTHESIA

LOCAL anæsthesia has never been really popular in this country, either among surgeons or their patients. There are times, however, when the patient must be kept awake; and then it may be a nice problem how to occupy his attention during the hours that the surgeon is operating. The usual practice has been to administer so much opiate or barbiturate or both that there is little attention left to occupy. This is not an entirely satisfactory solution, because many intelligent patients would prefer to be more aware of their surroundings. Entertaining and interesting conversation is another solution, and surgeons have even employed special assistants solely for this purpose. Thus Pitkin[1] speaks of his "auburn-haired vamp who has the faculty of making a woman forget that she is in the operating-room and causes her to imagine she is attending a musical or a bridge party. In some unknown way she causes the children to desert their own mothers for her, and she makes the men feel that the operation could go on forever if she would only remain with them."

Music as an aid to local anæsthesia was suggested many years ago. In latter years more than one hospital in Britain has had its theatres "piped" with radio, but the patients often preferred not to have the earphones on—like people in the "blitz" who, when radio or gramophone was being played to relieve the strain, would say, "Please turn the thing off. I can't hear what is going on." In the U.S.A. the use of music in the operating-theatre is being re-investigated.[2] In a Chicago hospital adults who are to be operated on under regional anæsthesia are asked the night before, "Will you have classical, semi-classical, or popular music tomorrow?" and children are offered a choice of "Cinderella," "Peter and the Wolf," or "Pinocchio." It is suggested that the right music lightens tension in the patient and also in the surgeons, who can talk more freely without the inhibiting influence of an attentive patient. As for relieving tension, it is said that Leonardo da Vinci, when painting La Gioconda, ensured that she retained her amused expression by having music played during the sittings.[3]

The truth probably is that during an operation under local anæsthesia each patient needs a divertissement suited to his particular temperament.

PROF. E. C. DODDS, F.R.S., will deliver the Bertram Louis Abrahams lecture at the Royal College of Physicians of London, on Thursday, July 13, at 5 P.M. He is to speak on the Bearing of Protein Structure on Clinical Problems.

THE CELEBRATIONS

The celebrations next week will take the form of a banquet when addresses of congratulation will be presented to the college, and on June 28 and 29 there will be special exhibitions on view. In the museum, the departments of anatomy and pathology will be staging exhibitions which will include examples of Hunter's originals and specimens made to replace those destroyed. There will be photomicrographs prepared for teaching purposes, and a series of radiographs of bone prepared by the type of X-ray tubes used in crystallography, which magnify without loss of definition and are stereoscopic. There will also be shown relics of the late war. These will be colour photographs including ones on the treatment of wounds and burns and the pathology of gas-gangrene. The museum has also acquired a number of specimens which will form a permanent record of the horrors of Belsen, including adult hearts about a quarter the normal size and weight. In the library will be an exhibition illustrating the research carried out at the college during the last 150 years.

REGISTRAR APPOINTMENTS

A SCOTTISH SURVEY

A review of the number of registrars in hospital appointments has now been completed by the Department of Health for Scotland. Read in conjunction with the earlier account of the number of consultants,[1] *it* leads to the conclusion that—in the words of the review—"the problem of reconciling the needs of the hospitals for medical staff with those of training for, and promotion to, specialist posts, both over the whole field and within the several specialities, has yet to be tackled. Its solution may well require a substantial change in present views and practices."

NUMBERS AND AGES

The survey, based on figures furnished by regional boards in the first three months of this year, shows that throughout the country there are 548 registrars of all grades. "The figures for each grade should be considered against the time normally spent in it: one year for junior registrars, two for registrars; and three or more for senior registrars—assume $3^1/_2$ years." At present junior registrars number 88; registrars 269, spread over two years, so that, with even distribution, there will be about 135 due to pass out of this grade each year; and senior registrars 191, of whom, presuming the spread to be over $3^1/_2$ years, 60 per annum will complete their course of specialist training. (The assumption here is that there is no "shedding" of senior registrars during their normal tenure.)

As regards ages, the year of birth of senior registrars ranges from 1900 to 1925; the year with the largest number is 1916 (corresponding to a present age of 34), with sharp declines in previous and later years. Of the 180 senior registrars whose ages are known, 139 are 32 or more years old; 7 are over 40, and the oldest is 50. The age-distribution of registrars and junior registrars generally follows that of the senior registrars at intervals corresponding to the time spent in the first two grades. Thus the years of birth of registrars are distributed round 1920 as a peak year (present age 30), with extremes at 1902 and 1924; and of junior registrars round 1922 as a peak year (present age 28), with much narrower extremes at 1916 and 1925. "All this represents a distinctly older population than the Spens report assumed in the training grades."

VACANCIES FOR CONSULTANTS

At the end of 1949, 646 consultants and 274 senior hospital medical officers were in hospital posts; and during the year 92 vacancies were advertised for these two grades together.

> "These advertised appointments represent in some cases replacements of specialists passing out of the Service and in others new appointments due to expansion of the Service, but they also include some vacancies arising from the movement of a specialist from one post to another. While they represent, therefore, rather more than the opportunities of promotion in Scotland for senior registrar, they do give a general measure of the prospects. In the first completed year of the Service, it is hardly to be expected that the appointment and promotion situation will set the pattern for subsequent years; it is too early to forecast the kinds of specialists who will be required for the hospital service in the next ten or twenty years. However, there may already be enough information to suggest that demand and supply are not yet equated."

The largest number of registrars of all grades is in general medicine (111), and general surgery (103), with 35 and 33 senior registrars respectively. The number in training in each specialty bears no close relation to the vacancies in Scotland.

> "In general surgery, with 103 registrars, including 33 senior registrars, there were only two specialist appointments advertised in Scotland during 1949. In orthopædic surgery only one post was advertised—the specialty has 27 registrars, including 11 senior registrars. By contrast there were 10 appointments in radio-diagnosis, which has only 16 registrars, including 7 senior registrars: and 10 appointments in psychiatry which counts only 34 registrars, 16 senior. In tuberculosis and chest diseases there were 11 appointments advertised—there are in this field 31 registrars, including 12 senior registrars."

CONTINUOUS SELECTION

The earlier memorandum suggested that the process of continuous selection of registrars for higher grades involved a "promotion pyramid," with the larger numbers in the junior grades progressively reduced to a comparatively small number regarded as fit to pass to consultant posts.

> "It is clear that this does not obtain today. Numbers of hospital medical staff assimilated to the Service after the appointed day were ex-Service men who had had considerable training, perhaps incomplete, and for whom the senior registrar grade was considered appropriate. In like case were some junior specialist staff holding quasi-substantive appointments before the inception of the Service, who were graded senior registrars. The result is that this grade now seems inflated in comparison to the other registrar grades, and as long as promotion from these grades is to be contingent on vacancies for consultants there may be very serious congestion.

The previous memorandum suggested a desirable distribution between the years of training, based on a yield of 30 trained specialists each year (which seemed a reasonable estimate of the number that might be absorbed in Scotland). The "desirable" and actual distribution is as follows:

Grade	*Numbers*			
	Desirable		*Actual*	
Junior registrars		90		88
Registrars:				
1st year	60		130*	
2nd year	40		139*	
		100		269
Senior registrars:				
1st year	30		50*	
2nd year	30		50*	
3rd year	30		50*	
4th year	30		41*	
		120		191
		310		548

* The distribution between years is only approximate.

---

151 and 117, and in 1949, 229 and 219. At present consultations are taking place between the English and Scottish corporations with a view to establishing a common standard for their fellowships (but not a common fellowship).

Some postgraduate demonstrations were carried on at Lincoln's Inn Fields before the war, but systematic teaching started since the war. Today the characteristic of the college is the number of young men and women of all colours and nationalities—and styles of dress—working in the museum and library, and attending the postgraduate courses. Last year something unique in conjunction with a medical corporation was inaugurated—the Nuffield College of Surgical Sciences. The provision of a residential postgraduate college has been made possible through the munificence of Viscount Nuffield, and when the special building, adjacent to the Royal College of Surgeons, has been built it will accommodate 100 men postgraduates; at present 20 are accommodated in a converted building, also next door to the college.

A hundred years ago Sir Richard Owen, when conservator of the Surgeons' Museum, delivered lectures on dentistry. In 1859 the college instituted the L.D.S., its first special diploma, and in 1947 it created an innovation by forming a Faculty of Dental Surgery and a Fellowship in Dental Surgery; in 1948 a similar Faculty of Anæsthetics was established. The college also grants, jointly with the Royal College of Physicians, eleven specialist postgraduate diplomas.

SCIENTIFIC WORK AND THE MUSEUM

Much scientific work is carried on under the auspices of the college. There are departments of anatomy and pathology at the college; the department of experimental research has the Bernhard Baron Research Laboratories and the Buckston Browne Farm; and the ophthalmological research unit was established in conjunction with the Royal Eye Hospital.

In 1799 the Surgeons Company wisely accepted the contents of John Hunter's museum which had been purchased by the Government and turned down by other scientific bodies. This formed the nucleus of the college museum which was built up into one of the largest medical collections. Among the distinguished conservators of the museum, two particularly stand out—Sir Richard Owen, in the 19th century, and Sir Arthur Keith in the 20th. In the days when presidents came and went each year, much depended on the permanent officials, and Owen was conservator for 30 years. He was especially interested in comparative anatomy, and tried to persuade the college to take over the Natural History collections of the British Museum. Quite properly the council considered this rather outside their scope, and so Owen, having persuaded the British Museum authorities to set up a special Natural History Museum, left the college and spent a further period as curator at South Kensington. Prof. G. Grey Turner has described the 26 years (1908–34) that Sir Arthur Keith was conservator as the heyday of the old museum.[3]

The destruction by bombing on the night of May 10, 1941, has proved to have been even more extensive than was thought. Only 3489 specimens survived out of a total of 11,225; and of 2671 Hunterian specimens, 1567 were saved.[4] But already much progress has been made in restoration of the collections, especially with a view to the requirements of postgraduate students.

THE LIBRARY

The library of the Royal College of Surgeons is 150 years old this year, for it was in July, 1800, that the first grant—of a sum not exceeding £50—was made for library purposes. Although in the early years considerable donations were made, the progress of the library for a quarter of a century was very slow. One of the LANCET letters, written by James Wardrop under the pseudonym "Brutus," said: "Some years ago Sir William Blizard [President, 1822] promised that the library should soon be opened. We are still outside the door, however, and a part of the bust of Sir William, like the molten calf of the Israelities, may go down our throats (by adulteration of bread or in the drinking of soda water) before we shall see a book, especially the Hunterian MSS." Two years later the first librarian was appointed.

The first of the great librarians of the college was Robert Willis, a physician; he prepared the first classified catalogue. In the 'nineties J. B. Bailey reorganised the library, and he was the first person to recognise the importance of periodicals; today the library is particularly rich in transactions and journals. Like the rest of the college, the library has changed with the times. With the expansion of the other great medical libraries in London—notably those of the Royal Society of Medicine and the British Medical Association—and also the libraries in the medical schools, which has taken place in the present century, it was realised that the purpose of the Surgeons' library needed to be redefined; and under the present librarian, Mr. W. R. Le Fanu, it has been developed as a library of surgery and the basic sciences; it also, of course, has a rich historical collection. Like the museum, the library has been affected by the growth of postgraduate teaching at the college, and it caters particularly for the postgraduate student.

SOCIAL ACTIVITIES

On the social side the college holds monthly subscription dinners. The Royal College of Surgeons Club, whose object is "to promote social activities for members of the medical profession within the college," has a luncheon-room in the basement. Within the precincts of the college there is maintained a joint secretariat for a number of surgical and medical societies, which are thereby afforded close association with the college.

THE BUILDINGS, OLD AND NEW

The first building of the Royal College of Surgeons was constructed at the beginning of the last century to the designs of George Dance, R.A. It soon proved inadequate, and was demolished and replaced in 1835 by a new building, which forms the greater portion of the present structure. This was designed by Sir Charles Barry, R.A., the architect of the Houses of Parliament, but he did not, fortunately, attempt a Gothic style which would have been most inappropriate, and he retained Dance's portico idea. Numerous additions and extensions have been made to Barry's building—in 1847, for instance, the Duke's Theatre in Portugal Street, where the *Beggar's Opera* had been staged, was pulled down for an extension of the museum.[5]

Today plans are ready for another great rebuilding. On an adjacent site now partly occupied by corrugated iron sheds which are used as an osteological store will arise the Nuffield College of Surgical Sciences. The ruins of the museum will be built upon. This will provide residential quarters for male postgraduate students, a modern lecture-theatre, and new museum and laboratory accommodation. In the existing building there will be an extension of the entrance hall and the reading accommodation in the library, at present often overstrained as a result of the number of students, will be enlarged. The whole will form an impressive "palace of surgery" worthy of the capital city.

---

[3] Grey Turner, G. The Hunterian Museum Yesterday and Tomorrow. London, 1946.

[4] Royal College of Surgeons of England: Scientific Report, 1948–49.

[5] Webb-Johnson, Lord. *Annals of the Royal College of Surgeons*, 1950, 50, 343.

This used to be my left thigh, but the place gradually rked up because it was a nuisance to have to take trousers down every time, and I now have an insensie bump just below my waist on my left side, which can get at by undoing about three buttons. (Just w insensitive the bump is can be gauged from the t that a needle lasts me normally about 18 months, ien the soft metal lining of the top wears out.) By ese methods, time and trouble devoted to care and intenance are reduced to a minimum, and diabetes s become barely a disability to me.

I had to give up schoolmastering, of course, when, r years ago, I was found to have bilateral pulmonary berculosis, the left lung being severely infected and e right slightly, and my sputum being positive. I nt home, but did not, after a preliminary skirmish, t myself under the appropriate medical authority, for rious reasons. I was not at all anxious to go to a natorium, which I was told to do, since I was certain at they would hold other views than mine about abetes. The treatment proposed was rest, which I as having at home under what were to me more pleasant rcumstances; and as my home was a small farm, ere was plenty of good food. I was not led to put uch trust in the probable results of sanatorium treatent in any case, and came to the conclusion that should not have been a very satisfactory patient. s it happened, within three months I was farming, and farmed for four years, and would still be doing so d it not been that for family reasons I was forced to ll the farm in September, 1949.

I have since been told that I ought not to have survived is wilful course. I did not see a doctor during these ur years, so I have no precise evidence of my condition, xcept that I certainly lost no weight and certainly ad no wish for another way of life. Of course I could ot work as hard as a healthy agricultural labourer, ut I surprised myself by what I could do. I tried o avoid the heavier work, but it wasn't always possible n a small farm, so I did my share of muck-carting, otato-lifting, and the more laborious jobs. I became uite good at tractor work, which is far harder work han it looks, and there was much light work connected with fruit trees and so on which was ideal for me. I ran short of breath pretty quickly, but then I would stop and get it back. I found no complication of diabetes through having tuberculosis, my established system continuing to run with its customary smoothness.

I don't want to encourage others to follow my lead about farming without proper thought; though I believe it offers a good life for any tuberculous person who can get about without running a temperature. But it can't be done without a great deal of careful reparation, and the most exact attention to detail in aving labour, time, and breath. Labour, machinery, method, type of farm, and the farm buildings must all e considered. Before embarking on such a venture ne should appreciate that there are many problems to urmount and more are bound to arise from each ndividual experience. But with ingenuity, intelligent lanning, and determination, a way can often be iscovered round, through, or over the most formidable bstacles.

For the next three months after leaving the farm, I moved about the country staying with friends, doing very little but considerably perturbed over my financial position (since the sale of the farm had been at the worst possible time for me, and such agreements as I had in writing unfortunately ensured that I bore any financial loss), and exceedingly unhappy over the curious manner in which it seemed to me my nearest and hitherto dearest had behaved. Moreover, for the first time I faced the social problems of tuberculosis, which had not arisen on the farm, where I hardly saw anyone unless in the open air. I did not in any case realise how serious the risk of infection was. I had at one time been given a booklet from which I learnt to cough into a handkerchief, not to spit, and to keep a window open in any room I happened to be in, and I was under the impression that if I did these things, I endangered none. By the end of the three months, I reached what I hope is my lowest ebb. I had worried about a stone-and-a-half of weight away; I had become fully aware of my social position, and couldn't begin to see where I was going to fit in ever again; I got a bad cold and lost my voice. Finally I had a handsome attack of flu while staying in a drab but expensive hotel. I had no wish to prolong my visit, so I did not retire to bed, but shamefacedly acquired a thermometer which made, at times, very interesting reading.

By this time I realised that I wasn't very well, and was even more worried about what I would find to do in the future, so I went to see a doctor who has been a friend of mine for a long time. I was duly X-rayed, and it was decided that I should find somewhere to live and do as little as possible for three months, and then be X-rayed again. I had no intention of going to a sanatorium, and this plan was just what I wanted to do, and I was prepared to invest the rest of my slender capital in it. It was an interesting three months. I found a one-roomed flat where I do my own cooking and housework, neither of which amount to much, though I am by nature fairly clean and I realise that food is important. I led an entirely selfish and timeless existence. I ate when I felt like it, rested when I felt like it and for as long as I wanted. There was no-one for me to worry about, and no-one to worry about me; that was easy.

Ever since I've had tuberculosis, though, I have found the mental part of it far and away the most important. I have never worried about my health, but worry over other things certainly affects my tuberculosis, and at this time there seemed to be plenty of other things. There was also plenty of time to give to them. Every man will deal with these things in his own way, but it seems to me vital to understand that they must be dealt with, or else they will have a bad physical effect. I began to improve rapidly once I was able to stop worrying and feeling depressed; but I had to make a sustained effort to achieve this. A recent examination has shown that I am making excellent progress and there is good reason to believe that I shall once more become a more or less useful member of society—an unbelievably entrancing prospect.

My course has been dictated by circumstances and my own temperament. I do not particularly recommend it, but it has its points, and my farming venture might well have turned out more successfully. It does show, too, that a man can do a great deal for himself in his own home; and I wonder how many people on the waiting-lists of sanatoria could, with a little guidance, be cured or put well on the way to recovery before their turn comes.

". . . In many of our small towns the inhabitants, with the enthusiastic support of their doctors, have built and equipped small hospitals with mutual benefit to all concerned. Now, in at least one region, some of these hospitals have been closed to the general practitioners who have staffed them for years. The consequence of this ridiculous step is particularly obvious in relation to midwifery. Now, a woman who for several good reasons, including the distance of her home from her doctor, wishes to have her baby in hospital but would like to be looked after by her own doctor cannot do so. One can scarcely imagine anything more calculated to depress the standard of general practice and discourage recruitment to its ranks than the deliberate exclusion of the practitioner from the hospital. It *is* a policy which should be completely reversed.—Dr. E. R. C. WALKER, *Edinb. med. J.* 1949, 56, 493.

As the survey observes, the prospects cannot be assessed from totals: numbers must be evaluated in relation to each of the specialties.

> “*If* and when the specialist replacement rate falls to something like 30 a year in Scotland, the figure previously indicated, *if* graduates in successive years are to have an equal chance of becoming specialists, and *if* the assumptions underlying the Spens Report are considered to hold valid, clearly a very considerable readjustment must be made. Either fewer individuals will have to be selected for entry to the registrar grades, or the passage through these grades will have to become progressively more difficult, otherwise the numbers completing training will be far beyond the ability of the Service to absorb them.”

Young doctors, says the report, will not indefinitely proceed up a blind alley. Sooner or later the evidence of disillusionment and disappointment among registrars and the poor prospect will dissuade many aspirants and reduce the numbers of those seeking registrar appointments; and it seems better that this readjustment should be made deliberately rather than be left to happen. “It is neither fair to the individual, nor good business, to train over a period of years, and at public expense, excessive numbers of aspirants who in the event cannot find places in their chosen field.”

Progressive selection of registrars for higher posts implies competition at the transition from junior registrar to registrar, and from registrar to senior registrar. Senior registrars who are unsuccessful in competition for specialist posts may now, in theory, have their appointments terminated as they run out. There is understandable reluctance to take such a course, which means the loss to the hospital service of a highly trained man, and perhaps the destruction of his hopes of a career in special work.

> “But if senior registrars are allowed to hold their posts beyond a set tenure, until they can obtain specialist posts, or the posts they desire, the number of vacancies in their grade, available for competition to other registrar grades, is by so much reduced. Progressive selection is unduly hampered, to the detriment of other aspirant specialists and eventually to that of the hospital service.”

EFFECTS OF REDUCING NUMBERS

If the numbers of registrars are to be reduced by restricting entry or by eliminating more at certain bars during the training courses, the result will be twofold: (1) as regards hospital staffing, the loss of men in training who are rendering valuable help in the regular work of the hospital will have to be offset by additional appointments of some other kind; and (2) those registrars who have been “shed” during their training will have to turn to other fields—often that of general practice. “It seems to follow from the second result that there would be good reason for adjusting the registrar curriculum so that it takes more account of the future requirements of the very considerable numbers—perhaps the majority—who will become general practitioners. Further, if the training in special subjects which has been given to such men is not to be wholly lost and unproductive, their attachment to hospital departments after they are in general practice would be of considerable mutual benefit, and might go far to promote the reintegration of general and hospital practice.”

The unrequited demand for specialists overseas and in the Services offers opportunities which “may have become temporarily overshadowed by the sweeping changes which have followed the inception of the National Health Service in the home country.” Nevertheless, this factor alone, the report concludes, cannot radically alter the position at home.

Disabilities

51. DIABETES AND TUBERCULOSIS

I GOT diabetes twenty years ago when I was a boy at a preparatory school. It was a great anxiety to my parents, and a severe blow to me as it was discovered three days before Christmas. I was sent to a nursing-home, put on to insulin and a rigid diet, and remember being exceedingly hungry. When I returned home, my mother looked after me, gave my injections, and tested my urine. A weighing-machine was installed in the dining-room, and I entered entirely into the spirit of the thing, keeping most rigidly to the rules. It took time to get used to a new sort of life, a very regular day being the most important thing, as otherwise the balance of insulin and diet became upset. Apart from the various limitations to what I could do, which at that age were irksome, the only thing I really minded, and which I continued to mind until I found how to disguise it, was being different from other boys, particularly not going to a public school, which did not seem practicable at that time. However I led a very pleasant life.

About two years later, my mother became much interested in Christian Science, and she interested me in it too. Eventually, under the influence of a doubtless well-meaning practitioner, my mother was persuaded to stop giving me insulin, and entrust the matter to God. Not surprisingly, God rejected the responsibility and reduced this proselyte to a skeleton. I went back to insulin, and had soon recovered.

Not so long after this episode, I began to look after myself, giving my own injections. I had long regarded the testing of my urine as unnecessary. According to the sugar content, so the colour of the solution alters from blue to green to muddy green to rust, and I had been able to forecast the colour for a long time with almost unfailing accuracy. I tested my urine once, broke the tube, and have never tested since. I made some mistakes later (though never serious ones), but that was because I was young and not prepared to pay proper attention to what I was feeling like. Now I have the thing to a fine art, and I think any reasonably intelligent person who wishes to save himself the trouble of testing could, by carefully noting his “feelings” and then comparing them with a urine test—and doing this possibly for a month or two—soon be able to do the same. I suppose the chief feeling is thirst, and this can be graded with practice to extreme nicety. I find it hard to list others; I have a certain sort of tired feeling and a dry feeling of the skin. I think anyone would soon find out his own feelings for himself. I imagine no-one has much trouble about knowing when he's had too much insulin. I save myself a great deal of trouble by this method; but I should add I have found doctors almost universally unsympathetic to the theory.

Having broken the ice, I gradually simplified the whole business. I gave up the weighing-machine and any pretence at diet. One of the reasons for doing this was that I became a schoolmaster at the age of eighteen, and being nervous enough in any case, the thought of about eighty pairs of eyes on a specially prepared dish—even if such had been forthcoming—and the uninhibited questioning of the young, filled me with a fearful terror. And, in fact, I liked treacle pudding.

My system has become one of the utmost simplicity. I use ordinary insulin, 80 units per c.cm., and give myself two main injections a day—one before breakfast, the other before supper—usually of 40 and 30 units, though foreknowledge of the menu may affect this. In the course of the day if I feel at any time that I want more insulin I have it. I carry insulin and syringe and glucose with me always, and inject in the same place every time.

In England Now

A Running Commentary by Peripatetic Correspondents

Now washing-day is bright and brisk
And Monday passes in a 'WISK':
Matron or virgin needs no urgin'
To chuck her woollies into 'STERGENE';
For whiter whites, the blithesome bride
Leaves everything to time and 'TIDE.'
Her nylons, if she's any left,
She deftly rinses out in 'DREFT,'
And fluttering outside her pre-fab
Are brighter coloureds washed in 'FAB.'
But Graves' the ailment that afflicts her.
As each advertisement depicts her,
With wide-eyed stare, with animation
Unnatural flushed, in conversation
With other too-ecstatic wives
Having the wash-day of their lives—
She'll soon have exophthalmic goitre.
Pray, Mr. Bevan, do not loiter:
To Monday's menace call a halt
By iodising table-salt!

Or, 'LUX' *ex-tenebris*, let's hope
That Maurice Webb de-rations soap.

* * *

This week the children retrieved my *Lancet* the moment t fell through the letterbox; last week they left it ying on the floor in the hall, where it was found by Dougal McPoodle, our puppy. (His mother was an Aberdeen; his father is known to have been "brown n colour and able to get under the garden gate," hitherto believed to be dog-proof.) Dougal evidently liked the ook of the *Lancet* and took it to a quiet corner to chew over the latest researches. Later my wife found the kitchen and scullery littered with small pieces of white paper, and in a corner lay the moist and macerated remains of Vol. CCLVIII, No. 6611. There was much laceration of the middle pages, some being torn out by the roots, so to speak, while others bore evidence of vigorous toothwork (canines, I presume), great semilunar segments having disappeared from the top corners. The cover pages and advertisements came through the ordeal fairly well, apart from some fancy fretwork here and there. Reading this number called for a combination of skilful guesswork and patient selection of the pieces of paper gathered from the kitchen floor. On the whole I managed fairly well, but give me a *Times* crossword any day for choice. Fortunately, our shaggy pup is a selective reader like myself. When I sought him out to administer reproof he did not seem the least ashamed. He lay on his back, pawed the air, and said in the way that shaggy dogs do: "When does the *B.M.J.* arrive?"

* * *

Fearful of getting a long neurological case at the forthcoming Membership examination, I trailed along to a neurological hospital for suitable instruction. Having arrived late, I hurried through the portals without finding out the subject for the afternoon's demonstration. I tried to creep in at the back unobserved but was publicly shamed by being given a seat in the second row, where I felt bound to be more than usually attentive. With glasses on my nose and notebook and pencil on my lap I prepared to gather some neurological pearls, but after a few moments, in which phrases like "dissociated personality" and "*la belle indifference*" kept cropping up, I realised that I was in for an hour's psychiatry. There was no escape—I clearly could not walk out after accepting the courteous invitation to sit in front—so I comforted myself with the thought that the examiners do occasionally ask psychiatry and settled down to listen.

The lecture, I now gathered, was on hysteria, but the two patients who were to illustrate the subject had apparently defaulted and a rapid glance outside likely doors failed to reveal them. As a consolation prize we were given their histories with all the gory and intimate details. Their characters were relentlessly dissected and their remarkable behaviour explained. It was while the first case was being dealt with that I noticed two middle-aged women sitting in front of me. One had an incredible hat perched precariously on the side of her head and kept twiddling her fingers. I said to myself, "She'll never pass the Membership." However, she seemed to be listening with great avidity to the lecturer's words of wisdom. "The second case," he was saying, "is one of hysterical coughing. . . ." At this the woman with the hat turned to her equally queer-looking neighbour and said, "That's me, Elsie." I was too dumbfounded to do anything but listen to the tale of marital unhappiness which had led to this hysterical symptom. The lecturer concluded by again apologising for the non-arrival of the patients, but this time the two women in front announced triumphantly and simultaneously, "We're 'ere: 'ave been all the time." With tremendous aplomb (only a psychiatrist could have done it) the lecturer mildly rebuked them, led them forth, sat them down facing the class, of which they had so recently been members, and demonstrated their various features. When this was over the patient with the hat was given a date for a future appointment with the distinguished psychiatrist, and as she reached the door she paused for an instant, smiled at us all, and said, "Thanks for the lecture. Ever so interestin' it was."

I feel sure that her husband's slumbers will no longer be disturbed by her hacking cough. Perhaps it is sound therapeutics to pop the patients into the audience occasionally. I must ask my psychiatric friends.

* * *

Our Public Health Department occupies a convenient but somewhat unhygienic position, in the centre of the town over the public lavatories. This juxtaposition, while helpful in directing strangers, is not to be commended. It has, for example, caused the administration and staffing of the lavatories to be a responsibility of the Health Department, and when the department lately advertised for a male lavatory attendant the following letter was received.

Dear Sir,—Can I apply for your post as lavatory attendant. I am a limbless ex-serviceman, from the first war, use a artificial leg, and also hard of hearing, but can manage all right. I would like a job to help me, as the pension alone will not keep me, do any kind of cleaning, clean, honest, and sex free, that is, do not bother about women. Age 50, lost my leg when 20 years old, single, non-smoker, and don't drink, only tea which is far better than beer, and trustworthy, on the King's Roll of Honour.

Thanking you kindly for a reply, I am, Sir . . .

The job, however, finally went to one of our quiescent tuberculous patients, whose name (appropriately enough it is Dan) I allowed to go forward somewhat reluctantly, having in mind the underground work. But my fears proved groundless, for Dan took to the job like a duck to water, and is successfully passing through his "Arrested" years with no inconvenience. The ammoniaco-carbolic odour in which he "works" seems to stimulate his resistance—a point perhaps worth taking up for further investigation?

* * *

A month or two ago I listened enthralled to Fred Hoyle's description of the universe on the Third Programme. So graphic, detailed, and confident was his account of the evolution and fate of suns and stars that one felt sure he had been present at the Creation and must hold a ticket for the End of All Things. Then today I found that my six-year-old son had written his name and address in one of my books in the cosmic style children sometimes affect, as follows:

SIMON,
35 ANEMONE CRESCENT,
LONDON,
THE WORLD,
WHOLE THING,
NUTHING,
Oh i dont know

A timid person myself, pleased not to know too much about these things, I prefer Simon's cosmology.

* * *

DEAR SIR (June 10),—LOCOS TENENTES please! I don't know who you hare but whoever you hare you're very higgorant.

Medicine and the Law

Surgical Operation as Technical Assault

If a plaintiff sues a surgeon in respect of an entirely successful operation for which no fee was charged and which the surgeon did not in fact conduct, it comes as something of a surprise to learn that the surgeon has committed a "technical trespass" and must pay damages, even though the sum is nominal.

Mr. Emanuel Michael, an antique dealer at Folkestone, sued Mr. H. W. L. Molesworth, the Folkestone surgeon. He said that the surgeon was recommended to him by his own doctor as thoroughly competent and experienced. He consulted the surgeon in December, 1947, in respect of an operation for hernia; the operation was successfully performed in the following March by the house-surgeon at the local hospital, but he complained that Mr. Molesworth himself had undertaken to operate on him for a fee of 25 guineas. His claim for damage was apparently brought in order to vindicate a patient's right to choose his own surgeon; "an apprentice practised his skill on me without my consent, when I had engaged a craftsman."

The defendant surgeon, Mr. Molesworth, denied the alleged agreement: the plaintiff, he said, had signed a document whereby he agreed to accept the ministrations of the hospital staff (including the house-surgeon): the operation was part of the services given by the hospital; the house-surgeon was a very able young man. Mr. Molesworth stated in evidence that he had never charged a fee to a patient in a public ward; Mr. Michael had asked him what was his minimum fee and he had replied that in a private ward it would be 25 guineas; there were no private wards in the local hospital at Folkestone; the nearest would be at Canterbury or Ashford.

Lord Justice Singleton, sitting as a trial judge, held that there was no breach of contract. Mr. Molesworth had said that he undertook no personal obligation in the case. The Lord Justice said he regarded Mr. Molesworth as a man of honour and a witness of truth; he probably did not realise in March that Mr. Michael expected him to operate personally. His lordship did not think Mr. Molesworth led Mr. Michael to believe that he himself would operate. The plaintiff's claim was unusual; he had had the benefit of an entirely successful operation at the hospital by a competent surgeon for no charge; he was thus 25 guineas better off than he might have been.

That might have been supposed to be the end of the litigation. The learned Lord Justice, however, held that, as the house-surgeon had operated without the patient's leave or licence, there had been a trespass—"a highly technical trespass." An unauthorised person had done an act which another person had been authorised to do, and the act had been done in a thoroughly competent manner; Mr. Michael had been treated with consideration everywhere; Mr. Molesworth had behaved properly, in accordance with his duties and his high professional standing; nevertheless there was a technical trespass for which the court awarded the nominal sum of 20s.

The result is puzzling. One would expect the claim for the trespass to have been brought against the house-surgeon, not against Mr. Molesworth; one would expect the document which Mr. Michael signed to have barred his claim. Lord Justice Singleton did indeed observe that the action ought not to have been brought. The plaintiff, he said, might well have recognised that the time of those like Mr. Molesworth, engaged in such work for the good of the people generally, could be better spent than in resisting claims of this nature: "I regret that the action was brought and persisted in."

The plaintiff's claim on the issue of breach of contract was dismissed with costs: his award of 20s. was with costs; a counter-claim for 3 guineas by Mr. Molesworth (as his fee for the December consultation) was allowed with such costs as were appropriate. Mr. Michael's claim to choose his own surgeon had not, in the court's opinion, been challenged. The trespass, since the Lord Justice had accepted Mr. Molesworth's account of the facts, remains something of a puzzle; but the case will serve to remind us all that any operation is an assault unless all proper consents have been obtained.

Public Health

Poliomyelitis in England and Wales

In the twenty-third week of the year, ended June 10, there were 79 (37) notifications of poliomyelitis—61 (27) paralytic and 18 (10) non-paralytic cases. Figures for the previous week are shown in parentheses, and it will be seen that these numbered slightly less than half of the total for the twenty-third week. In the twenty-first week notifications numbered 50—34 paralytic and 16 non-paralytic cases. Geographically, there is a clear preponderance of cases in the Midlands, with 22 notifications in Warwickshire and 9 in Staffordshire.

This rise in notifications has come earlier than usual, and 79 is probably the highest figure ever recorded in a twenty-third week. It is, however, not possible to be certain about this since the change in categories of notification introduced this year makes exact comparison impossible. It is too early to tell whether this early rise presages an incidence of the order experienced in 1947 and 1949, or whether the experience of 1948 is more likely to be repeated. In 1948 there was no clear-cut epidemic, but the curve of summer and autumn prevalence was protracted and flattened. In that year the incidence rose to 31 cases in the twenty-fifth week, remained about 30–45 cases until the thirty-third week, then rose to 78, and remained at about that level until the forty-fourth week after which it slowly declined.

Travelling Exhibitions on Cleanliness

The film *Another Case of Poisoning*[1] will be shown in conjunction with three travelling exhibitions on Health and Cleanliness which the Central Office of Information is preparing for the Ministry of Health. The exhibitions may tour for two years. They are designed for showing to workers in the food and catering industries, in canteens, and to organisations such as women's institutes. Display sets of twelve pictures, 15 in. by 12 in., have also been prepared, and may be shown by firms and other bodies which apply.

Census in 1951

A draft Order in Council which has been laid before Parliament outlines arrangements for the next census in Great Britain. This is to be held on April 8, 1951; and censuses are expected to be held on the same day in Northern Ireland, the Channel Islands, and the Isle of Man.

The inquiries proposed for 1951 are somewhat more extensive than those in 1931, when the last census was held. Information is to be obtained on the distribution of the people by area, sex, age, and marital condition; the size and composition of households; where people were born, where they live, and where they work; what their nationality is; their occupations and industries; whether they are still at school, college, &c., or, if they have finished whole-time education, at what age they finished; whether the dwelling is structurally separate, how many rooms it has, and whether the household has or shares a piped water-supply, a kitchen sink, a cooking-stove, a water-closet, and a fixed bath. Married women under 50 are to be asked the date of their marriage and the number of children.

The complete analysis of the returns will be spread over many years, but a preliminary return by numbers, sex, and areas will be published within a few weeks of census day.

[1] See *Lancet*, Jan. 14, p. 96.

ıe digits amputated for various disorders, was not able ı demonstrate the Sucquet-Hoyer canals before the ȝe of 4½ months. He found that they are less frequently found in the arteriosclerotic; and that they ·e opened up in certain inflammatory states.

The reason for the lowering of the blood-flow after ıe sixth day after operation is not quite so easy to ꞔplain, but the active dilatation of the muscular and astic tissue of the glomus is not likely to persist :definitely. Furthermore the glomus is under the ıntrol of tissue metabolites,[8] alteration of which would ːcessarily affect the patency of these canals. Such ı alteration includes stagnant hypoxia of capillaries stal to the anastomosis and "hyper oxia" of the veins. 'ith regard to the case described by Mr. Lynn and r. Martin—a multiple ligation of varicose veins in a g whose veins were not competent, accompanied by mbar sympathectomy—I suggest that such a combined ɔeration is automatically followed by the persistent rcing of arterial blood into the veins, which, being :cluded, can never empty. It is doubtful whether ıis procedure has much to support it—except possibly some chosen cases of thromboangiitis obliterans.

London, N.7. I. H. MILNER.

WHOLE-WHEAT BREAD

Sir,—Any ordinary consumer may obtain wheat grain, ' flour, direct from the grower, thus ensuring unadulter- ed whole-wheat. The ideal is to grind at home, fresh r each baking (this contributes much to the wonderful ıvour). For those who cannot manage this, freshly 'ound flour can be obtained; and bread made from it now available, too. It is more expensive from home- ound flour, because there is no subsidy, although on ıtional bread, containing adulterants, the subsidy is 6*d*. ɛr 3½-lb. loaf.

ENERAL ANÆSTHESIA FOR BRONCHOGRAPHY IN CHILDREN

Sir,—In your issue of June 10, Dr. Way and Mr. ames describe their method of anæsthetising children ɔr bronchography. Whilst ready to admit that their ɛchnique may give satisfactory conditions in their own ʞpert hands, I feel that the authors should be upbraided ɔr not stressing in any detail the inherent dangers of ıe operation as a whole, and for recommending an ıæsthetic agent which is notoriously unsuitable for ıch cases, without a note of why its contra-indications ·e ignored.

The corner-stone of any anæsthetic, especially for a agnostic or therapeutic procedure, must be "safety." gainst this, thiopentone as the sole agent for straight- ɪrward intubation, even in adults, may readily be ɔmplicated by cough and laryngeal and bronchial ɔasm. In the presence of excessive bronchial secretions, hen the narrow bronchial tree in children may so easily ɜ completely obstructed, this technique is foolhardy. he dosages of thiopentone mentioned may be danger- ısly large in themselves as depressants for small children ith respiratory pathology. Again, premedication is not iscussed, though it must obviously, I hope, not be a ɑrbiturate.

In my opinion, the administration of anæsthesia for ronchography should be undertaken only by experienced ıæsthetists, and I would warn any unsuspecting col- :agues that in such cases a dose of thiopentone in inexpert ands will sooner or later result in disaster to the patient.

R. B. WRIGHT
Anæsthetist.

DAIRY-GOAT'S MILK

Sir,—Increasing numbers of medical men are prescribing goat's milk for patients. Almost all the milk from my dairy-herd, whose annual yield is roughly 4000 gallons, goes to invalids. When the characteristics of goat's milk are studied, one wonders why the milk of the cow is ever used for human consumption.

The goat is almost immune from tuberculosis; the very rare cases recorded in goats have nearly all been traceable to the fact that they had been reared on cow's milk or had been in contact with tuberculous cattle. Nowadays goatkeepers do not use cow's milk for rearing kids; and fortunately, it appears that goats that do contract tuberculosis invariably die of the disease, thus preventing their use for breeding purposes. Of 77,000 goats slaughtered in the U.S.A. in one year, not one was condemned as tuberculous.[1] Over one-third of our dairy cows are tuberculous, and these diseased animals are still being used for breeding.

Ease of assimilation is probably the greatest point in favour of goat's milk for invalids. The fat globules are only about one-eighth the size of those of cow's milk, and the curd of the milk is softer and more open in texture. The cause appears to be the greater amount of salts of sodium and potassium, especially citrates, in the milk of the goat as compared with the milk of the cow.[2]

The following are averages for the composition of cow's and goat's milk, based on analysis of some thousands of samples:

	Milk, constituents (%)	
	Cow's	*Goat's*
Fat	3·67	4·50
Lactose	4·78	4·08
Casein	2·63	2·47
Albumin and globulin	0·60	0·43
Non-protein nitrogen compounds	0·19	0·44
Lime	0·18	0·19
Phosphoric acid	0·23	0·27
Total mineral constituents	0·73	0·79

There is no reason to suppose that the vitamin content of goat's milk is inferior to that of cow's milk.

There is a common belief that goat's milk is "strong" in flavour, or "smelly." This is untrue. Goats, like cows, if badly fed and tended, will produce tainted milk. A well-tended herd of either cows or goats will produce milk completely free from objectionable flavours and smells.

Two years running at the Essex County Agriculture Show, a test was carried out in which hundreds of people unknowingly participated. Members of the public were invited to sample the milk from each of two pails and to record their preference. One pail contained goat's, and the other cow's, milk. On balance, there was little difference in the popularity of the two; but some who had pronounced in favour of goat's milk stated that they would not have drunk it had they known it was goat's milk.

Ample supplies of good, clean, dairy-goat's milk are available throughout the country. More than 4000 goatkeepers are registered with the British Goat Society and the affiliated county societies; and probably double this number are not registered. The bulk of the milk is being used, not medically, but for the manufacture of ice-cream, cheese, and so on. Perhaps doctors are not taking full advantage of these supplies because they are unaware that goat's milk is obtainable, or because they are under a misconception as to its purity and value. I will gladly supply to doctors or hospitals the address of the secretary of the nearest county society, who will be able to give the names of reliable goatkeepers in the area.

Letters to the Editor

DANGERS OF THE MUCUS CATHETER

SIR,—I should like to draw attention to some dangers associated with the mucus catheter so frequently used on the newborn infant.

The mucus catheter, if correctly used, should be a safe instrument for removing mucus and other secretions from the upper air passages of the asphyxiated baby. The catheter lies ready sterilised in a covered dish during delivery so as to be available for immediate use if necessary. It is sterile on the first occasion it is inserted into the baby's mouth, but is by no means so on subsequent insertions.

Many a time I have seen a catheter allowed to trail over unsterile bedsheets, blankets, and towels so that after the initial sterile insertion a large number of organisms are introduced by the instrument into the baby's upper respiratory passages and pharynx. Moreover, the catheter is frequently passed much too far down and in some cases would appear to reach into the œsophagus—surely not only a useless but also a dangerous procedure. This direct implantation of organisms may result in virulent pneumonia or gastro-enteritis; recently I have seen some seriously ill babies with these infections in whom the source of infection was in all probability the mucus catheter.

I feel that teachers of medical students and midwives should point out these risks and should impress upon them:

1. Not to use the mucus catheter as a routine measure (a procedure I have noted in many hospitals and nursing-homes). It should be used only if the mucus cannot be removed by posture or the baby's own efforts.
2. Not to pass the catheter further than the pharynx. (It might be worth while putting a mark on the catheter 2 in. from the tip so that it cannot be passed too far).
3. To wipe the end of the catheter, after each insertion, on some sterile material.
4. To avoid contamination of the catheter with unsterile objects, and to lay it on a sterile towel during use.

London, N.W.2. M. E. LANDAU.

THE SIGNIFICANCE OF EOSINOPHIL-COUNTS

SIR,—Your leading article of June 3 has done a great service in drawing attention to the use and difficulties of eosinophil-counts. There are some points of importance, however, which I feel ought not to be passed without comment.

In the first place, Fin Rud's[1] extensive work is rightly quoted, but his results are accepted quite uncritically. Like Thorn and Forsham in Boston and Prunty in this country, he uses a modification of Dunger's technique for the direct counting of eosinophils. However, as pointed out by Randolph,[2] the solution used lyses not only the red cells but also the white. As anyone who has used this technique will realise, one must not shake the pipette containing the blood and dilution fluid for more than about 30 seconds before transferring the contents to the counting chamber. If very much longer than this is taken for mixing, no eosinophils can be found, and it is doubtful whether adequate mixing can be obtained in this short time. Certainly in my hands this method of counting not infrequently has yielded results which were obviously erroneous. A further point of criticism is that Rud counts only the cells in one Fuchs-Rosenthal chamber, whereas it is quite possible to fill eight such chambers from one white-cell pipette, thereby increasing one's accuracy nearly threefold.

Dr. Janet MacArthur, Dr. Donald Harting, and myself, working at the Massachusetts General Hospital, have modified the technique described by Randolph,[2] propylene glycol to render the red blood-c invisible. The details of this method will be p elsewhere, but the advantages are that no lysis of cells occurs, that the total white-cell count can be in the same chamber as the eosinophil-count, and that the mixture of blood and dilution fluid can remain for a considerable time in the white blood-cell pipette without detriment.

Using this technique, and counting the cells in eight chambers, a spontaneous fall in the eosinophils of a normal person of the degree quoted by you *may* occur betwe 10 A.M. and 2 P.M., even if that person is kept under bas conditions, but I should be very surprised if it did very commonly. In any event, using this counting technique, the four-hour adrenocorticotropic-hormone (A.C.T.H.) test described by Forsham and his colleagues[3] has been found to give quite reliable results in clinical practice, there being even some relationship between the eosinophil fall and the clinical response of an arthritic patient to A.C.T.H.

Finally, may I use this opportunity to deprecate the use of such expressions as "40 to 228 per c.mm. should be regarded as the normal range for males . . ." Until there is a generally agreed convention as to what constitutes a "normal range," such of that precision of meaning with scientific terminology.

CIRCULATORY CHANGES AFTER SYMPATHECTOMY

SIR,—I was greatly interested in last week's articles by Mr. Lynn and Professor Barcroft, and by Mr. Lynn and Mr. Martin. I suggest that in all the cases described the effects are due chiefly to the direct transference of arterial blood to the veins as the result of the opening up of the arteriovenous communications which occurs after sympathectomy. Modern textbooks of physiology have paid insufficient attention to the work of Claude Bernard[4] on the effects of cervical sympathectomy. This great French physiologist wrote:

> ". . . quand on a préablement coupé le grand sympathique dans la région moyenne du cou . . . la circulation s'accélère considérablement, la température augmente, le sang veineux devient rouge, la pression augmente. Si l'on vient à galvaniser le bout périphérique ou supérieur du sympathique, la circulation diminue d'intensité, les vaisseaux se resserent, et la température baisse en même temps que le sang devient très noir. C'est particulièrement sur les chevaux où tous ces faits se présentent avec une grande évidence."

It is probable that corresponding effects are produced in the vessels (and blood) of the limbs when their sympathetic nerves are similarly affected.

Sucquet[5] quoted Claude Bernard in his own classical monographs on arteriovenous communications—subsequently known as Sucquet-Hoyer canals[6]—and offered reasonable data to indicate that these become opened up in conditions of cachexia and after a rapid and prolonged phlebotomy. Sucquet found that after injecting fluid into the arteries of the limbs of the cadaver, the fluid reached the corresponding veins at rates which would not allow for its passage through capillaries. In the case of the lower limb, "il revient plus vite et plus abondamment par la veine crurale que par la saphène"—suggesting even greater numbers of these communications in deep than in superficial vessels. Popoff,[7] who examined

Africans in Kenya are nearly always infested with hookworms and/or other helminths, and we have put forward the view that worms may interfere with the synthesis, absorption, or utilisation of hæmopoietic principles, and give rise to this aberrant picture (cf. *Dibothriocephalus latus* anæmias). The factor of diet probably enters the picture. Years ago Gilkes and Orr found significant differences between the hæmoglobin level of the vegetarian Kikuyus and the blood- and milk-taking Masai. We think the fact that many of the cases respond to marmite is not without significance.

Whatever the cause of these megaloblastic anæmias among Africans, it seems clear that peripheral bleeding due to worms is not likely to produce the marrow picture that we are finding here, although as stated above worms may be playing their part. In the frank hypochromic microcytic anæmias that exist here worms may play an important part.

Regarding gastric function, a great number of our cases show hypochlorhydria after histamine, but we have so far not found a histamine-fast achlorhydria. Our feeling is that this question is an important one.

The low gastric acidity in so many of our cases may contribute to the low hæmaglobins that we are finding with colour indices of 0·4 and M.C.H. as low as 9·0–11·0 micromicrogrammes. The very low-protein diet of some of the tribes with which we are dealing may also be an important factor in the deficient synthesis of hæmoglobin. There may however be another factor, which we are investigating, that may have a bearing on these profound iron-deficient anæmias. This is the possible iron loss in the sweat of races whose sweat glands have the formation found in the Negroid races of torrid Africa. Mitchell and Hamilton[3] have shown that the iron loss in the sweat may increase from 13% to 40% of the iron intake under hot humid conditions (cf. Stewart et al.[4]). How far the iron-deficient anæmias in the hot humid areas of the East Coast of Africa and on the shores of Lake Victoria are due to hookworms, poor diet, achlorhydria, and loss of iron in the sweat is now being examined. It is significant that the hot humid areas of Africa are generally centres of high hookworm and malaria incidence.

As you state in your leading article, the time may have come to revise our conception of the megaloblastic anæmias, and we suggest that with the production of such substances as folic acid and B_{12}, with others no doubt to follow, the time has already arrived when we can look upon the megaloblastic macrocytic anæmias as having a different ætiology from the megaloblastic normocytic anæmias, and fit into the picture the presence or absence of the giant stab-cells.

WEAR AND TEAR

SIR,—I have not the ability to dispute the argument of Lord Moran's stimulating paper last week, but I feel it not unfair to remind him that *Henry V* was probably written about 1598—i.e., three and a half centuries ago instead of five as stated—and that in spite of the theory that Shakespeare himself saw military service, it is doubtful whether he had as good opportunity personally to observe the morale of the men of Agincourt (1415) nearly 200 years before as had Lord Moran to observe that of the men of the Royal Fusiliers.

I would suggest that yokels even in the Middle Ages need not be presumed to have vacant minds without better evidence than this.

Amble, by Morpeth,
Northumberland.

R. P. ROBERTSON.

ANOMALIES OF SALARY

SIR,—In your leading article of May 20 you commented on the poor rates of remuneration of Civil Service medical officers. In fact their salaries contrast sharply with the Spens recommendations, the starting-point being in most cases lower than that offered to senior registrars. Moreover, as you note, the majority of Civil Service doctors are excluded from the recommendations of the Chorley report because their salaries are not over £1500.

We are told that our conditions cannot be improved because of the wage-freeze. Nevertheless salaries have been substantially improved for many of our colleagues in the National Health Service and in the medical schools. Most of us on appointment were required to have special knowledge and experience, and many of us are engaged solely in responsible clinical work. The low salary-scale has led many doctors to leave the service, whilst others are deeply dissatisfied and are seeking alternative employment.

The B.M.A. has refused to accept advertisements for the service, but we note that you have decided to publish them. This, to us, amounts to condoning the salary-scale and denies us your practical support in our attempt to obtain conditions comparable with those of other medical men. We have for a long time been employing the methods of negotiation used by educated men. These methods have got us nowhere, and we remain the poorest-paid group of experienced doctors in the country.

Whilst we appreciate your clear statement of your attitude and your sympathy for us, we feel that in this matter, as in others, an ounce of help is worth a ton of pity.

SIX CIVIL SERVICE MEDICAL OFFICERS.

*** Our help so far has taken the form of explanation and comment, which are the normal functions of a journal. On Jan. 14 and May 20 we drew attention to the damage now being done to the Government medical services, and the anomalies of remuneration in them; and we pressed for an unprejudiced inquiry, which we believe would have better results than a few episodic concessions by the Treasury. We differ from our correspondents only on method. At the present time especially, we are uneasy about any ready resort to measures other than "the methods of negotiation used by educated men."—ED. L.

USE OF POLYESTER RESINS IN MEDICINE

SIR,—Dr. Scales (June 10) says that if I was "concerned with scientific advancement," surely my methods of bone-casting should be published. In the article in *British Plastics* (December, 1949) which he mentions, full data are given as to the materials used—which information is sufficient for the informed readers of that specialised technical journal to "reconstruct" the process. In an article in the *British Medical Journal* (Feb. 25, 1950) the method of moulding (viz., in polyvinyl chloride copolymer), and the materials used for casts, are given. This article further states that other moulding and casting methods are being developed. Is one, at an experimental stage, to give incomplete details, including trade names of compounds used (as done by Dr. Scales)? Surely the usual principle is that the really interested reader writes to the author for further information, which, of course, is always fully given. (Incidentally I *did not* myself write either of these articles.)

May I add a few words on the question of who carried out the pioneer work in plastic bone-casting? Though many workers may have occupied themselves with the same problem, I do not know of others having taken this fascinating idea to its logical conclusion—namely, to the making of the fully *articulated skeleton*. I shall be most interested to learn of any achievement in this field, if for no other reason than to enable a fraternal

THE MEGALOBLASTIC ANÆMIAS

SIR,—We have read with great interest the papers by Israëls and Sharp and Tuck and Whittaker and your leading article in *The Lancet* of April 22, and should like to make the following observations.

In previous communications[1] we have described megaloblastic anæmias that are not macrocytic, and macrocytic anæmias that are not megaloblastic. These findings raise the question of the origin of macrocytosis and the fate of the megaloblast (cf. Fruhling and Spehler[2]). From our investigations it appears that the following combinations may exist in the megaloblastic and/or macrocytic anæmias.

(*a*) An anæmia with, say, red-cell counts between 0·5 and 1·0 million per c.mm. in males or pregnant or non-pregnant females; with typical Ehrlich's megaloblasts and giant stab-cells in the sternal marrow (Riesen stab-kern of Schulten; giant metamyelocytes); with high M.C.V., M.C.H., M.C.H.C., and C.I.; Price-Jones curves well to the right of normal; with a high percentage of macrocytosis, raised M.C.D., M.C.A.T., and abnormal volume-thickness ratios. There may be a raised indirect van den Bergh, and a positive Schumm's test. The cephalin-cholesterol, thymol turbity, bromo-sulphthalein clearance, plasma proteins and ratios, and colloidal gold may be normal or abnormal. Such anæmias respond to crude or refined liver, to folic acid, and more slowly to 'Marmite' in large doses or a high-protein diet. These anæmias are similar to those that have been described in Macedonia and elsewhere.

(*b*) Anæmias with counts between 1·0 and 1·5 million, with Ehrlich's megaloblasts and giant stab-cells in the sternal marrow but with *normal* M.C.V., M.C.H., and M.C.H.C., with Price-Jones curves within normal limits, no macrocytosis, normal M.C.D., M.C.A.T., and volume-thickness ratios. Liver function may be normal or abnormal. These cases respond as do those in group (*a*). So far they have been described only here and in Bechuanaland.

(*c*) Anæmias with counts between 1·0 and 2·0 million, with no Ehrlich's megaloblasts in the marrow but with giant stab-cells. The M.C.V., M.C.H., M.C.H.C., and diameter distribution may be raised or normal. These cases also respond as do the two previous types.

(*d*) Anæmias with neither megaloblasts nor giant stab-cells in the marrow, but with raised M.C.V., M.C.H., M.C.H.C., and C.I.; Price-Jones curve to the right of the normal span; macrocytosis and raised M.C.D. and M.C.A.T. There is generally liver involvement, and the response to treatment is rarely satisfactory, no doubt because of the underlying condition.

The existence of these anæmias, some of which have megaloblasts and/or giant stab-cells in the sternal marrow, with or without macrocytosis, has led us to postulate three factors as responsible for the conditions:

(1) A red-cell maturation factor, the absence of which leads to abnormal maturation of the red-cell line in the marrow and the production of Ehrlich's megaloblasts.

(2) A white-cell maturation factor, the absence of which is responsible for the production of giant stab-cells.

(3) A diameter-controlling factor. We are aware that there are numerous factors concerned with the regulation of cell size. We are of the opinion that this aspect of the question requires considerably more attention than it has so far received, especially in view of the emphasis that hæmatologists often placed on the phenomenon of macrocytosis.

The factors postulated above are by no means always jointly absent, as is shown by the different types of anæmia that occur.

In pernicious anæmia, folic acid produces a response in the hæmatological condition but leaves the nervous symptoms untouched; liver deals with both symptom complexes. It is now reported that in idiopathic steatorrhœa large doses of 'Anahæmin' leave the megaloblasts untouched. This is indeed quite extraordinary when one considers the rapidity with which these cells disappear in pernicious anæmia and the nutritional macrocytic anæmias. Are the megalob of idiopathic steatorrhœa in some way physiologically different from other megaloblasts? If so, this is an observation of considerable interest and significance. Is it possible that there may also be similar differences in the response of the giant stab-cells in different forms of anæmia, or in the responses to different pure substances such as folic acid and vitamin B_{12}?

The giant stab-cells that occur in many of the dyshæmopoietic anæmias have not, we think, received the attention due to them by the British and American workers; Continental workers are familiar with these cells and do not neglect to comment on their significance. In our opinion these giant stab-cells are just as pathognomonic as are the megaloblasts of Ehrlich, and indicate an upset in marrow maturation of the white-cell series, as the megaloblasts indicate a defect in red-cell maturation. It is still not realised by many writers that the megaloblast is a pathological cell, and is not to be confused with early and late erythroblasts. We recently read an article in which the author naively stated that megaloblasts were not as numerous in his normal controls as they were in his patients!

As was pointed out some years ago, sternal biopsy as an aid to hæmatological diagnosis has become a very popular procedure, but unfortunately proper methods of staining, and discriminating diagnosis are neither so common nor so popular, and we sometimes question whether the observers are really aware of what they see or are looking for, and whether the results they obtain justify the use of this not unpainful technique.

Perhaps we have been fortunate in the countries in which we have done our work, in that we can keep our patients under observation in hospital for five or ten days before we commence any specific therapy. This may not always be possible, but we would like to point out the great importance of this procedure. We believe it involves no extra risk to the patients, who have generally been in their anæmic state for weeks or months, often going about their daily affairs; to keep them under observation in bed for a few days is unlikely seriously to affect them. The discordant reports regarding the effect of vitamin B_{12} in the nutritional macrocytic anæmias makes us wonder whether perhaps more discriminating procedures would have yielded less contentious results.

Perhaps we have also been fortunate in not being obliged to resort to what may be called the "neo-polypharmacy." If such treatments as blood-transfusions, liver, folic acid, marmite, B_{12}, &c., are all given to the patient within a few days, the results are of questionable value. Our own procedure is to give one form of treatment only, and to continue this until it has become clear that no response is to be expected, to wait for a few days watching the reticulocytes, red-cell count, and Hb, and then to commence with the new form of therapy.

Whatever the relation that may exist between the M.C.V., M.C.D., M.C.A.T., Price-Jones curve, and the reticulocyte level, there can be no question that the M.C.V. should be taken at a low reticulocyte level. More often than not the M.C.V. is given without any reference to the level of reticulocytes. The correlation between these five variables may turn out to be not always positive.

It is not sufficient, in our opinion, to base a diagnosis of a macrocytic blood picture on slide examination, M.C.V. or high C.I. Price-Jones curves should be prepared if an accurate picture is desired. Unfortunately diffraction methods for estimating cell diameters cannot be substituted for the time-consuming and laborious Price-Jones curve.

The megaloblastic macrocytic and megaloblastic normocytic anæmias that we are dealing with among the

Muscular Dystrophy

. R. H. TURTON asked the Lord President of the Council research was being conducted into the origin of and cure uscular dystrophy.—Mr. HERBERT MORRISON replied: rch on the muscular dystrophies forms an important of the work of the Medical Research Council's neuro- al research unit at the National Hospital, Queen Square, lon.

Voeller Treatment of Parkinson's Disease

. JOHN ARBUTHNOT asked the Minister of Health whether as yet in a position to make a statement on Dr. Voeller's ment for Parkinson's disease.—Mr. BEVAN replied: group of patients who went to this clinic under observa- have now been re-examined a year after their treatment . I am advised that the methods used by Dr. Voeller ine an intensive rehabilitation course with drug treat- and diet. These methods do not constitute a cure, lo they introduce any new principles, but in the small le of cases investigated they modified with varying of success the steady deterioration which is the al progress of the disease, and encouraged patients ntinue their own efforts to improve.

Anthrax

answer to a question, Mr. TOM WILLIAMS stated that in and there were 108 outbreaks of anthrax in 1947, 95 in , and 204 in 1949, and there have been 149 so far this year. ough outbreaks have occurred in the majority of counties have been most numerous this year in Lancashire and Vest Riding of Yorkshire. It is probable that the increased ence of anthrax is due largely to the increased imports rtilisers and animal feeding-stuffs from abroad.

Education of Deaf Children

eplying to a question, Mr. GEORGE TOMLINSON said that anuary, 1949, there were, on average, 10 8 pupils in class for the deaf or partially deaf. The increase in school accommodation during the past two years had led places to be found for an additional 200 deaf children, unfortunately, owing largely to the increasing apprecia- that deaf education should begin at a very early age, was still a waiting-list of some 450 children for deaf ols. Everything possible was being done to expedite osals for further deaf school accommodation in the next or two. The accepted policy of separating the education ne partially deaf from that of the deaf was being carried as far as the existing accommodation permitted. A small ease was being made in the provision for deaf children ring from a second defect, and he looked forward to further osals as soon as the shortage of ordinary deaf school es had been substantially reduced. Deafness was cted in the schools at the periodical medical inspections, pecial medical inspections to which individual children been referred by their teachers or by the school nurse, by group audiometer tests. Facilities for the treatment iseases which might cause deafness were available through school health service and the National Health Service.

Institutional Care of Mental Defectives

r. D. J. LLEWELLYN asked the Minister of Health why late Lily Irene Palmer, a mental defective, had been arge for three years prior to being murdered; how many tal defectives were known to be at large; and how many nese had been awaiting admission to institutions for one or longer.—Mr. BEVAN replied: This girl had been mmended for institutional care when a suitable vacancy d be found. She was a borderline case for which admission n institution was not regarded as urgently necessary, and had not been certified under the Mental Deficiency Acts. ording to returns by local health authorities, the number nental defectives awaiting admission on Jan. 1 last was . The returns do not indicate how many had been ing for one year or longer.

Osteopathic Treatment

r. PETER FREEMAN asked the Minister of Health how far opathic treatment was available for all those who wanted nd particularly in hospitals.—Mr. BEVAN replied: Osteo- y, as such, is not provided in the National Health ice.

Obituary

WILLIAM FREEMAN SNOW

M.A., M.D. STANFORD

A VERY wide circle of friends in the U.S.A., in Britain, and in most other countries will be grieved to learn that on June 12 Dr. W. F. Snow, chairman of directors of the American Social Hygiene Association and president of the Union Internationale contre le Péril Vénérien, dropped dead in a street at Bangor, Maine.

William Freeman Snow was born in 1874. After graduating as B.A. in chemistry at Stanford University and becoming later M.A. in physiology, he qualified M.D. in 1900. Subsequently he studied at Johns Hopkins and other institutions in the U.S.A. and elsewhere. He very quickly joined the teaching staff of Stanford University, and from 1902 to 1919 was professor of preventive medicine there; from 1908 to 1914 he was State health officer, California. In these offices he quickly became known as a man of energy, tact, and wisdom, and in 1913 he was persuaded to undertake the direction of the newly formed American Social Hygiene Association.

This now-powerful organisation owes its origin to such men as President-Emeritus Charles W. Eliot, of Harvard, and Dr. Prince Morrow, of New York, who were then leaders of organisations trying to promote sex hygiene, as also to President David Starr Jordan, of Stanford University, who then headed a movement against commercialised prostitution. These and others, seeing the need for a voluntary agency with the broadest possible approach to the problems of social hygiene, merged several existing societies together to form the A.S.H.A.

In 1917 Snow became principal adviser on the prevention of venereal diseases to the American Army, on its entry into the war of 1914–18; and concerning this phase of his work, Prof. C. E. A. Winslow, of Yale, said in a public address about fifteen years ago: "In this whole first phase of practical diseases control in the United States, William F. Snow was the stage manager, even though he rarely occupied the limelight in his own person." Dr. Maurice A. Bigelow, in a short biographical sketch accompanying invitations to a commemorative dinner to Dr. Snow in 1937, said: "The amount of labor he performed was colossal. He seemed to be driven by some high compression engine denied to other men. In fact his nickname was 'Driven Snow.'"

From 1924 to 1928 he was chairman of the League of Nations Committee to Study the Traffic in Women and Children, and from 1947 until his death he was president of the International Union against Venereal Diseases. Besides these offices he held many others, as professor or lecturer in preventive medicine in different universities, as chairman of various bodies interested in public health, and as adviser to the U.S. Public Health Department. Throughout, his work was actuated by the principles of preventing infection through education, medical care, wholesome occupation of leisure, and repression of commercialised prostitution.

The affection and esteem of his associates were expressed magnificently at a dinner in New York on Oct. 1, 1937, when over 400 guests met to present him with a bronze portrait plaque, "on the occasion of his fortieth year of distinguished service to education, public health and social hygiene." Many speakers, including the late Sir Arthur Newsholme, testified to Dr. Snow's courage, energy, single-minded honesty of purpose in the service of mankind, and modesty. There were 27 cables and 116 letters from people unable to attend the dinner. The speeches and other communications were published in the souvenir number of the *Journal of Social Hygiene* (December, 1937), and to the writer of the present tribute it was comforting to find "how did you do it?" to be asked between those concerned.

Those interested in the history of anatomy (and workers in this field ought to be) know that the first skeletal model—the model of the skull—was reported to have been used in the teaching of anatomy by Henri de Mondeville, surgeon-anatomist of Montpellier, in the 14th century. As Mondeville was a pupil of the Italian Lanfranchi, it is conceivable that he was not the first. Jumping a few centuries (which is a pity, because it is quite conceivable that the genius of Leonardo da Vinci, to whom anatomy owes so much, produced artificial bones) we come to the Italians Fontana and Mascagni in the 1780s, producing wonderful plastic replicas of all sorts of anatomical specimens, many of which can still be viewed (without admission fee being charged) at the Dorotheum in Vienna and in the Department of Anatomy in Budapest.

The 19th century was not sterile in this field, either. As early as 1828 a "complete anatomy in papier mâché" was announced, containing over 1000 parts, many of them presumably bones. Later in the 19th century the now famous modelling houses of Gerrards of London, Deyrolle of Paris, and Sommer of Sonningen in Thuringia (to name but the few leaders in the field) produced some bones in artificial material, soi-disant plastic.

Let us, therefore, be humble in fighting about 19th-century priorities. Some may have produced bones in modern plastic materials before me; I do not know. I presented the first plastic bone, made by a member of my research team (*a lance-corporal in the Royal Army Dental Corps*) *at the Middlesex Hospital Medical School during 1943, to* Professor Kirk at the department of anatomy.

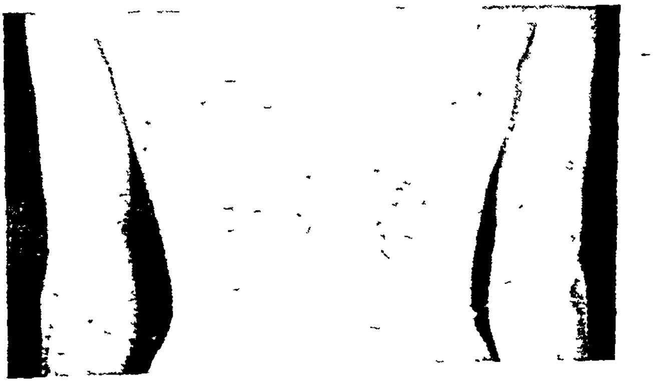
Let me end by making a plea not to confuse technical advances with the advancement of science. The making of artificial bones in one material rather than another is an adaptation of technique; the real scientific advance in this field has been made by the plastic chemists, who have given us materials of incredible versatility.

Sutton, Surrey. GEORGE BLAINE.

STRIÆ CUTIS DISTENSÆ

SIR,—Recently it has been said that 'Cortisone' can produce striæ of the skin[1]; and that the effect varies with the intensity of treatment and its cessation.[2] These observations "would indicate that in any patient in which coloured lineæ distensæ appeared, or were present, it can be concluded with a reasonable measure of confidence that the adrenal glands are secreting an excess of cortisone, and that their hyperfunction is therefore playing an important part in the pathology of the condition observed."[3]

I once regarded purple striæ distensæ as of major importance for the differential diagnosis of Cushing's syndrome[4]; but I was persuaded that this view cannot be upheld, and Cushing, in the course of correspondence, confirmed this view.



The accompanying illustration is from a (I also possess a lantern-slide in colour) of a young who first came under my care in April, 1941, was 20.

He was a tall, slim, well-built youth, with lobar A few weeks later he developed extensive purple distensæ on his back. In 1945 I encountered him by chance. He had remained in excellent health, complete investigation showed no signs of any condition. The purple striæ had only slightly faded. him under observation until 1947, without any the condition.

Albright and his associates[5] have suggested a general theory of the pathogenesis of Cushing's with the exception of the hyperpiesia. They pos protein wastage in the course of gluconeogenesis. other effects, this is said to cause a thinning of skin with the appearance of striæ and redness. has remained, however, a hypothesis, "and further presuppositions for its support."[6]

London, S.W.3. V. C.

DRUGS IN PARKINSONISM

SIR,—In your leading article of June 17, imme after your comment on the value of adminis mephenesin by mouth, you state:

> "More serious disadvantages of mephenesin are overdose may cause respiratory paralysis for which seems to be no effective antidote."

The extensive literature of work on m ('Myanesin') does not support the implication respiratory paralysis is in fact likely to occur on administration to patients, and certainly not when given by mouth. Indeed in the same issue of LANCET Dr. Armstrong Davison states on p. 1131 "despite large dosage of mephenesin continued several days, it has no obvious adverse effect" and p. 1132 that "the action of mephenesin is such antidote is required."

Parliament

QUESTION TIME

Distribution of Merit Awards

Mr. CHARLES TAYLOR asked the Minister of Health wh he expected to receive the report of the committee n sitting to deal with merit awards for medical consultants Mr. ANEURIN BEVAN replied: I expect to receive a rep within the next three months.

Mr. TAYLOR: Is it not intolerable that this class of c sultant should be left in such a state of uncertainty for long?—Mr. BEVAN: This is entirely a professional matt It has not been determined by me at all. It would have be even more intolerable if by hasty action the wrong peop had been selected.

S.H.M.O. and Consultant Status

Dr. REGINALD BENNETT asked the Minister to what exte medical officers graded senior hospital medical officer we thereby rendered ineligible for promotion to consulta status.—Mr. BEVAN replied: Not at all. Dr BENNET Would the Minister not agree that the interpolation of th grade between the grade of senior registrar and that consultant looks extraordinarily like a device for obtaini the service of specialists at cut rates? No further reply w given.

B.C.G. Vaccine

Mr. P. F. REMNANT asked the Minister whether he h considered the merits of B.C.G. vaccine as a tuberculo immuniser; and whether he would make it available to t public.—Mr. BEVAN replied: A trial use of the vaccine being made for selected cases, but I am advised that it wou not yet be suitable for indiscriminate use.

Notes and News

TRAINING OF LABORATORY TECHNICIANS

EGULATIONS and syllabuses of an intermediate certificate mination for laboratory technicians have been recently pted by the City and Guilds of London Institute. The me, prepared by the institute's advisory committee on ratory technicians' work, which is composed of repre- atives of twenty-five interested bodies, is designed to t the needs of laboratory technicians in schools, technical eges, universities, industrial organisations, and research ciations. It was drawn up on the suggestion of the Com- tee on the Education and Training of Laboratory Tech- ans, which, in 1946, was appointed by the Association of ntific Workers, the Association of University Teachers, the British Association of Chemists.

he scheme aims at providing an all-round training, as l as training special to the particular type of laboratory hich the student is attached, while special consideration iven to the technician who may wish to change in the rse of his training from one type of laboratory to another. course is part-time and occupies a period of three years, uiring attendance for approximately 180 hours per annum. the end of the three years the candidate will be eligible sit for the examinations, which will be held annually in at Britain and Ireland at any place at which the local cation authority or the governing body of any university niversity college accepts responsibility for their conduct, ell as at approved centres in the Commonwealth countries the Crown Colonies. In addition, local college examinations be held at the end of the first and second years. There be special facilities for those external students whose ndance at a scheduled course of instruction has not been sible. The scheme comprises a general syllabus for all didates, including one on general laboratory techniques, kshop practice, and photography and projection, and a ial syllabus for each of the following specialties : physics ; mistry ; biology ; physiology and pharmacology ; anatomy ; nal house ; mechanical engineering ; electrical engineering ; metallurgy.

ACHIEVEMENTS AT CROYDON

roydon Hospital Management Committee is evidently one those which have set themselves to win the sympathy and port of local people ; for it holds an annual public meeting, its report on the past year is well designed to catch the and the imagination. Thus under " additional services " find succinctly listed some of the improvements lately de. These include extended arrangements for occupational rapy and for showing films, the opening of a shop for ients at one of the hospitals, and the inauguration in the e hospital of an internal bank. But no attempt is made to the pill. Mr. D. A. Lawrence, the chairman, writes : ly committee deeply deplore . . . that they were not wed to continue the prenursing training scheme organised conjunction with Croydon Education Committee. The ult of this embargo has meant the loss of a considerable nber of potential nurses for the Croydon group."

iversity of Cambridge

n June 8 the honorary degree of D.SC. was conferred on W. S. Middleton, F.R.C.P., president of the American lege of Physicians and dean of the medical school of the iversity of Wisconsin.

n June 10 the degree of M.D. was conferred on A. G. E. rse and Ashton Miller.

iversity of London

he title of professor of pharmacology has been conferred Dr. J. M. Robson in respect of the post held by him at y's Hospital.

Dr. E [illegible] in pharmacology Gu [illegible] of the University Leec [illegible] use-appointments the Leeds General Infirmary and at the Leeds Hospital for omen before he became an assistant in the department of surgical earch and later in the department of physiology at Leeds. In 0 he was appointed assistant at the Institute of Animal Genetics Edinburgh, and when in 1932 he was awarded a Beit fellowship, continued to work there and later at the department of pharma- ogy of the University of Edinburgh, where in 1936 he was ointed lecturer. He is the author of *Recent Advances in Sex Reproductive Physiology*.

Mr. George Brownlee, D.SC., has been appointed to the [illegible] King's College from Oct. 1

University of Sheffield

Dr. E. J. Clegg, Dr. J. A. Howarth, and Dr. F. R. Johnson have been appointed demonstrators in anatomy. Dr. H. F. West has been appointed part-time clinical teacher within the department of medicine, and Mr. J. G. Napier part-time tutor in obstetrics and gynæcology.

University of Edinburgh

Dr. David Whitteridge has been appointed to the chair of physiology in succession to the late Prof. W. H. Newton.

Dr. Whitteridge, who is 38, received his medical education at the University of Oxford and King's College Hospital, London. He graduated B.M. in 1937, and the following year he was appointed a demonstrator in physiology at Oxford, and he is now a fellow and lecturer of Magdalen College. His work as a Beit fellow and as a Schorstein fellow has dealt mainly with the physiology of the nervous system. In 1946 he took his D.M. He is senior secretary of the Physiological Society. He was also one of the Oxford team which carried out experiments for the Ministry of Home Security on the physiological effects of blast.

The Wellcome medal and prize (£25) in the history of medicine for 1950 has been awarded to Dr. H. P. Tait for his essay on the Early History of Pædiatrics. The subject chosen for 1951 is Hippocrates in the Light of Modern Medicine. Further particulars may be had from the dean of the faculty of medicine.

University of the West Indies

Dr. E. K. Cruickshank, lecturer in medicine at the University of Aberdeen, has been appointed to the chair of medicine at the new university at Kingston, Jamaica.

Dr. Cruickshank, who is the son of Prof. John Cruickshank was educated at Aberdeen Grammar School and the University of Aberdeen, where he graduated M.B. with honours in 1937. He spent a year as a research fellow in surgery at Harvard University before he was appointed to the department of medicine at Aberdeen as assistant. In 1940 he joined the R.A.M.C. and he was for three years a prisoner-of-war in Japanese hands. For his work before and during captivity he was twice mentioned in despatches. In 1946 he read a paper on his experiences to the Nutrition Society and he described in our columns painful feet syndrome. He took his M.D. with honours in 1948 and his M.R.C.P. the same year.

Beit Fellowships for Medical Research

The following awards have been made :

FOURTH YEAR FELLOWSHIP

G. WEBER, PH.D. To study the dissociation of insulin : at the school of biochemistry, University of Cambridge.

JUNIOR FELLOWSHIPS

J. CROSSLAND, M.A. Oxfd. To study the nature and functions of humoral factors in nervous transmission in the brain : at the neuropsychiatric research centre, Whitchurch Hospital, Cardiff.

JOAN E. KEILIN, M.B. Camb. To study the link between the hæm and protein in hæmoglobin : at the school of biochemistry, University of Cambridge.

R. J. SALTON, Bac. Agric. Sc. Sydney. To study the chemical and immunological nature of the outer envelopes of bacterial cells : at the department of colloid science, University of Cambridge.

Faculty of Homœopathy

At a meeting of the faculty to be held at the Royal London Homœopathic Hospital, Great Ormond Street, W.C.1, on Thursday, June 29, at 5 P.M., Dr. G. Pampligione (Bologna) will give an address on the Clinical Uses of Electro-encephalography.

Conference on Preventive Medicine

The South Wales branch of the Socialist Medical Association is holding a conference on preventive medicine at the Y.M.C.A. Hostel, Rhoose, near Barry, on Sunday, July 2. The speakers will include Dr. J. B. Atkins, Dr. T. Francis Jarman, Dr. A. S. Jarman, and Dr. S. Leff. Tickets may be had from Mr. L. R. Fletcher, National Council of Labour Colleges, 321, Cowbridge Road, Cardiff.

Salaries for Senior Nursing Staff

The Nurses and Midwives Whitley Council have announced that revised salary scales have been agreed for senior nursing staff in general and fever hospitals and sanatoria. The new scales are part of the general review of nurses' salaries which has been proceeding for some time and they have retrospective effect from Feb. 1, 1949. Details will be published as soon as possible. The new scales cover all senior staff in these hospitals except tutorial grades, which are now being considered by the council. The scales for senior staff in mental and maternity hospitals are also under consideration.

Association of Clinical Pathologists

The summer meeting of the association will be held on July 20, 21, and 22 in the medical school of the University that all expressed in effect the spirit of his own contribution to the symposium:

> "It was high time that Dr. Snow was dragged into the limelight, so that he may feel the esteem in which those best qualified to judge his work hold him, and a wider public may learn something of what society owes him for the great part he has played in the campaign against venereal diseases and the traffic in women and children. Just before I first met Dr. Snow, at the birth of the League of Red Cross Societies in Cannes in 1919, I heard one of the American leaders speak of him as a man who, in the long run, achieved his objective, whatever the obstacles, without fuss and often without anyone being conscious of the solvent process that had been at work on the opposition. I think events have shown that judgment to have been pretty correct. Snow and I, with such distinguished men as Roux and Ducrey, were members of the V.D. committee of that Red Cross conference at Cannes, and it ended in the two of us *drafting the resolutions.* At least Snow did the work, and I, knowing that he would get his own way about them eventually, meekly agreed. It must be very gratifying to him and to you all, his associates in the fight you have waged so long against V.D. in America, to see its importance being recognised at long last by the general public."

In the years since then nothing has occurred to alter those sentiments. It may be added that Dr. Edward L. Keyes, in presenting the plaque, said: "I have been asked, my dear Dr. Snow, to present this plaque to the most modest and the most diplomatic man I know."

Dr. Snow is survived by his widow and two sons.

L. W. H.

After the presentation to Dr. Snow in 1937, the American Social Hygiene Association set up the William Freeman Snow Award, to be made from time to time "for distinguished service to humanity" in the field of social hygiene. The recipients have included Mrs. Neville-Rolfe, Colonel L. W. Harrison, F.R.C.P.E., and Sir Sidney Harris.

EDWARD BURTON GUNSON

M.D. EDIN., F.R.C.P.

Dr. E. B. Gunson, who was for many years in consulting practice in Auckland, died in Melbourne on June 4; at the age of 67. He was born in Auckland of English parents and he came to Britain for his medical education. After he graduated at Edinburgh in 1910 he held house-appointments at the Children's Hospital, Shadwell, and the West End Hospital for Nervous Diseases. When war broke out in 1914 he was research assistant in the heart department of the London Hospital, and he spent the next four years serving with the R.A.M.C. in the Middle East.

In 1919 he returned to Auckland, where he was for a time physician to the Auckland Hospital. He practised as a consultant in general medicine, but he was especially interested in cardiology. A past-president of the Auckland division of the British Medical Association, he also served from 1929 to 1938 as a member of the Auckland hospital board. A forceful public speaker, he held office on many public bodies, including the Society of Arts, the Open-Air Schools League, and the Crusade for Social Justice. Latterly he had served under the Commonwealth government in the Northern Territory.

Dr. Gunson is survived by his wife and daughter. His brother, Sir James Gunson, was a former mayor of Auckland.

ARTHUR DE WINTON SNOWDEN

C.B.E., M.A., M.D. CAMB.

Dr. A. de Winton Snowden, who died on May 20 in Bournemouth, at the age of 77, was the son of Prebendary J. H. Snowden, vicar of St. Paul's, Hammersmith. He was educated at St. Paul's School and Christ's College, Cambridge, where he was captain of his college boat-club. He rowed in the trial eights, but he just missed rowing in the Oxford and Cambridge boat-race.

Soon after qualifying from St. George's Hospital in 1897 he developed symptoms of tuberculosis, and in 1898 he went out to South Africa, as resident medical officer at Grahamstown Hospital, Cape Colony. For his services during the South African war he was awarded the Queen's Medal with four bars. After his return to England, symptoms of his disease recurred, and he went to Nordrach upon Mendip, first as a and afterwards as medical officer. In 1907 he staff at Mundesley, where he worked in close cc with the late Vere Pearson. In the 1914–18 war served as major *in charge of the* medical section of Red Cross Hospital *at Netley*, and for his services was appointed C.B.E. After the war he purchased, developed, the *Linford Sanatorium* at Ringwood the New Forest, where he carried on a most useful successful *practice.* On *his retirement* he settled Bournemouth. A friend adds: "Snowden will be remembered by *a large* number of appreciative grateful patients, and sadly missed by a im number of old friends. These regrets will be shared any young children *of his acquaintance.* With them was always at his best."

He married Miss E. C. *Drummond*, who died in the daughter of Captain Cecil Drummond, of Enderby Leicester. His only son, born in 1912, survives him.

KENNETH McALPINE

M.B. GLASG.

Dr. Kenneth McAlpine, senior school medical for Leicester, died in hospital on June 11. He grad at Glasgow in 1917, and served for a time with R.A.M.C. After demobilisation he held appointm the school medical services at Birmingham and on-Trent before he joined the staff of the L education authority in 1924 as assistant school officer. In 1946 he became senior school medical and he had to handle the many fluctuating of the post-war years.

A. J. S. writes: "Dr. McAlpine was an able efficient administrator dealing with the health well-being of the city's child population. To thousands of people in the city, as well as to his friends, he was much more than that. His nice sense punctilio in administrative affairs could never mask kindly, generous *nature* of the man himself. His fessional experience among children must have unique; his personal dealings with each one of young and old, was of a texture not found in books stemmed from his deep love of children and his own charm. By those of us who worked with him and his supervision—clerical staffs, nurses, professional leagues—Dr. McAlpine will be remembered with and lasting affection. To all who sought his advice any time, he was an immediate guide, counsellor friend. But beyond those, there must be thousands Leicester who, meeting him as children and now gr up, would wish to pay generous tribute to a fine doct and a most lovable personality."

Births, Marriages, and Deaths

BIRTHS

CRAWFORD.—On June 13, in Liverpool, the wife of Dr. F. J. *Crawford—a son.*

GOLBERG.—On June 16, in London, the wife of Dr. Boris Golbe —*a* son.

HARKNESS.—On June 13, in London, the wife of Dr. R. D. —*a daughter.*

LESTER.—On June 16, at Solihull, Birmingham, the wife of M Stephen Lester, F.R.C.S.E.—a son.

MCLAREN.—On June 16, in Udayagiri, India, the wife of Dr. D. McLaren—a son.

ORMROD.—On June 12, at Boney Hay, Walsall, the wife of Peter Ormrod—a son.

PINKERTON.—On June 9, at Worcester, the wife of Dr. J. R. Pinkerton—a son.

PITT.—On June 13, at Watford, the wife of Dr. Peter Pitt daughter.

RAMSAY.—On June 3, in London, the wife of Mr. Gordon Ram F.R.C.S.—a daughter.

THOMPSON.—On June 13, in London, the wife of Mr. Vernon Thompson, F.R.C.S.—a daughter.

WARREN.—On June 9, at Arundel, the wife of Dr. J. N. Wa —a son.

WINTER.—On May 31, in Bristol, the wife of Dr. George Win —a son.

WOLFSON.—On May 26, in Birmingham, the wife of Dr. L. Wolfson—a daughter.

WOOTTON.—On June 3, in London, the wife of Dr. I. D. P. Wootto —*a son.*

DEATHS

MCKENDRICK.—On June 5, John Wellesley McKendrick, M.B. Glas aged 35.

PHILLIPS.—On June 9, at Pinner, Albert Edward Phillips, M Dubl., surgeon commander, R.N. *retd.*

West London Medico-Chirurgical Society

The annual general meeting of the society will be held on Friday, June 30, at 6 P.M., at the West London Hospital, Hammersmith, London, W.6

Royal Society

On Thursday, June 29, at 4.30 P.M., at Burlington House, Piccadilly, London, W.1, Prof. J. Z. Young, F.R.S., will deliver the Ferrier lecture on Growth and Plasticity in the Nervous System.

British Spas and Health Resorts

On Thursday, June 29, at 4.30 P.M., a meeting of medical and non-medical men and women is to be held at 11, Chandos Street, London, W.1, to consider setting up an association for the study and development of British Spas and health resorts. Dr. A. P. Cawadias is the acting hon. secretary, and he may be addressed at 6A, Bourdon Street, W.1.

Memorial to Professor McMurray

A fund is being raised to commemorate "the services of the late Prof. T. P. McMurray who by his skill as a surgeon and as a teacher enhanced a great tradition." It is proposed to offer the fund to the University of Liverpool for the establishment of a prize for clinical work in orthopædic surgery, to be associated with his name. Contributions may be sent to Mr. Bryan McFarland, Department of Orthopædic Surgery, the University, Liverpool.

Kathleen Schlesinger Fellowship

The Medical Research Council invite applications for this fellowship from research-workers who wish to investigate the mechanisms underlying degenerative processes affecting the brain. The fellowship will ordinarily be tenable whole-time at the National Hospital for Diseases of the Nervous System, Queen Square, London, for one year in the first instance, renewable annually up to a maximum of three years in all. The stipend will be from £700 to £1000 per annum. Applications should reach the secretary of the Council, 38, Old Queen Street, S.W.1, not later than July 15.

Free Hospital Library Service to End

The *Times* (June 14) reports that the Order of St. John and the British Red Cross have decided to discontinue the free library service which they have offered to all hospitals since the end of the first world war. After consultation with the Ministry of Health it has been decided to ask hospital management committees, from June 30, for a contribution of about 1*d.* for each occupied bed. The decision does not apply to Forces' hospitals, at home or overseas, or to the Ministry of Pensions hospitals. Disabled ex-Service men and women in their own homes will also continue to receive free library facilities.

Convalescent Home for London Hospital Patients

The Marie Celeste Samaritan Society of the London Hospital has bought a large house at Woodford for the accommodation of patients from the London Hospital. The society, which does not come under the jurisdiction of the National Health Service, has redecorated and equipped the house. This home can now take 17 patients who no longer require hospital treatment but are not yet fit to go home or who may have no suitable home. The hospital allows any patient to return to the wards who is found to need further treatment. The house has been open only a few weeks but it has already proved its worth by setting free beds at the hospital. The North-East Metropolitan Regional Hospital Board has agreed to make a grant towards the cost of patients who are entitled to treatment under the National Health Service. The cost for patients who are not entitled to free treatment by the National Health Service will be borne by the Samaritan Society. The home has been named the Hora Home in memory of Mr. James Hora, the husband of Marie Celeste, who was a benefactor of the society.

International Congress of Ophthalmology

In connexion with this congress which is to take place in London from July 17 to 22, an exhibition of industrial and social ophthalmology is to be held at the London School of Hygiene, Keppel Street, W.C.1. The exhibition, which deals with the prevention of accidents and the promotion of visual health and safety, will be open on Friday, July 21 (9.30 A.M. to 6 P.M.), and Saturday, July 22 (9.30 A.M. to 1 P.M.).

Ministry of Health Appointment

Mr. F. L. Edwards has been appointed to the p under-secretary for finance and accountant-general i Ministry of Health, in succession to Mr. H. H. George, retiring on July 5.

Claims to Sickness Benefit

In England and Wales new claims to sickness benefit the National Assistance Act during the weeks ended 9, 16, 23, and 30 were as follows: 115,200, 111,500, 1 101,600, and 79,400 during May the weekly a was 100,500. The weekly averages in months from 1949, to April of this year were: 97,700, 83,500, 88,800, 100,900, 119,100, 136,200, 96,700, 154,900, 17 181,000, and 116,000.

The next television programme in the series *Matters of Life and Death* is one on Peptic Ulcers on M June 26, from 8.45 P.M. to 9.30 P.M.

Appointments

COHEN, E. LIPMAN, M.B. Camb.: consultant dermatolo Margaret's Hospital, Epping.
HEADON, M. F., M.B. N.U.I., B.SC.: appointed factory Tilbury district.
KEATES, G. H. W., M.B. Lond., D.A.: consultant ana County Hospital, Huntingdon.
MARSHALL, J. K., D.M. Oxfd, D.P.M.: consultant psych St. Audry's Mental Hospital, Woodbridge.
PARK, T. M., M.B. Glasg.: appointed factory doctor, Ca district.
REYNARD, A. L., M.R.C.S., D.A.: senior registrar in ana Norfolk and Norwich Hospital.

Colonial Medical Service:

GILCHRIST, K. J., M.B. Lond., F.R.C.S.: surgeon sp Nigeria.
HOWELL, A. T., M.B. Camb., D.T.M.: director of medical Tanganyika.
NEVILL, LESLEY, M.D. Edin., D.T.M.: M.O., Kenya.
NICHOLAS, G. J., M.R.C.S.: government M.O., British Gu
VAUGHAN, C. J. R., M.R.C.S.: M.O., Somaliland Protecto
YOUNG, W. B., B.M. Oxfd, D.T.M., D.M.R.E.: specialist rad *Singapore.*
